James, Henry, New York City; Columbia University College of Physicians and Surgeons, New York City, 1907; formerly on the faculty of his alma mater; fellow of the American College of Physicians; member of the Medical Society of the State of New York; veteran of World War I; a founder of the Doctors Hospital, where he was a consulting physician; consulting physician at the Southampton (N. Y.) Hospital and the Roosevelt Hospital; served on the staff of the Bellevue Hospital; died July 14, aged 76.

Bechtold, Edmond ⊕ Belleville, Ill.; Washington University School of Medicine, St. Louis, 1915; fellow of the American College of Surgeons; veteran of World War I; a member of the Belleville Township Board of Education; past-president of the Belleville Branch, St. Clair County Medical Society; held the Silver Beaver Award of the Boy Scouts; a director of the First National Bank; on the staff of St. Elizabeth's Hospital, where he died July 16, aged 65, of coronary thrombosis.

Eagle, Arthur Bruce, Martinsburg, W. Va.; University of Maryland School of Medicine, Baltimore, 1904; an associate member of the American Medical Association; past-president and secretary of the Eastern Panhandle Medical Society; city and county health officer; past-president of the West Virginia Horticultural Society; on the staffs of the City and Kings Daughters hospitals; since 1946 president of the Peoples Trust Company; died July 22, aged 76, of coronary disease.

Hutchinson, Alfred Dunbar, Pennington, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; an associate member of the American Medical Association; past-president and secretary of the Mercer County Medical Society; formerly practiced in Trenton, where he was a member of the board of education, an examining physician for the Selective Service, and on the staff of the Mercer Hospital, where he died July 5, aged 83.

Maroon, Sam Zacharia ⊕ Kingston, N. Y.; University of Cincinnati College of Medicine, 1941; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; interned at the Cincinnati General Hospital; served a residency at the New York Post-Graduate Medical School and Hospital in New York City; veteran of World War II; on the staffs of the Benedictine and Kingston hospitals; died July 20, aged 43, of coronary thrombosis.

Allen, Robert Wilson, Omaha, Neb.; St. Louis University School of Medicine, 1910; served as director of the Lee County Health Department while in Dixon, Ill.; veteran of World War II and the Korean War; died July 16, aged 68, of myocardial insufficiency.

Anderson, Bruce ⊕ Pontiac, Mich.; Detroit Homeopathic College, 1900; fellow of the American College of Surgeons; formerly practiced in Detroit, where he was on the staff of the Grace Hospital; died in the Pontiac General Hospital July 4, aged 83.

Andrews, William Arthur ⊕ Johnson City, N. Y.; Syracuse University College of Medicine, 1911; on the staff of the Charles S. Wilson Memorial Hospital, where he died July 11, aged 70, of pulmonary tuberculosis.

Antweil, Abraham ⊕ Fort Worth, Texas; University and Bellevue Hospital Medical College, New York City, 1918; member of the American Academy of General Practice; associated with the John Peter Smith and St. Joseph's hospitals; died in the Harris Hospital July 16, aged 62, of feticulo-endothelial sarcoma with metastases to liver, spleen, and heart.

Arline, Thomas J. ⊕ Cairo, Ga.; Louisville (Ky.) Medical College, 1893; on the staff of the Grady County Hospital, where he died July 7, aged 90, of uremia.

Baird, James Webber, Sadieville, Ky.; Cincinnati College of Medicine and Surgery, 1889; an associate member of the American Medical Association; died in Veachland June 25, aged 91, of arteriosclerosis.

Ball, Thomas Zopher ⊕ Crawfordsville, Ind.; Rush Medical College, Chicago, 1895; past-president of the Montgomery County Medical Society; member of the Association of Military Surgeons of the United States and the American Public Health Association; veteran of the Spanish–American War and World War I; served on the staff of the Culver Hospital; died June 19, aged 89.

Bates, Willard Allen, Madison, Wis.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1907; veteran of World War I; member of the House of Delegates of the American Medical Association from 1933 to 1935; fellow of the American College of Surgeons; died July 10, aged 80.

Beard, James Harvey, Sulphur Springs, Ark.; Memphis (Tenn.) Hospital Medical College, 1900; died July 8, aged 86.

Beazley, William Herbert, Baytown, Texas; University of Louisville (Ky.) Medical Department, 1912; served as state health officer; died in the San Jacinto Memorial Hospital July 11, aged 71, of myocardial infarction.

Blake, James Roscoe, Baltimore; Meharry Medical College, Nashville, Tenn., 1924; died in the Johns Hopkins Hospital June 27, aged 59, of micrococcal septicemia and pneumonia, and diabetes mellitus.

Boyd, Augusto Samuel ⊕ Panama, Republic of Panama; Columbia University College of Physicians and Surgeons, New York City, 1899; fellow of the American College of Surgeons; member of the Medical Association of Isthmian Canal Zone; died June 17, aged 77, of a heart attack.

Breath, Marshall Burt ⊕ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1940; specialist certified by the American Board of Internal Medicine; veteran of World War II; on the staff of the Baptist Memorial Hospital; died July 15, aged 41, of myocardial infarction.

Burns, Samuel Lee, Stonewall, Okla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; an associate member of the American Medical Association; died July 5, aged 81.

Carter, Roscoe Owen, Shreveport, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; member of the Louisiana State Medical Society; served as parish coroner; died July 7, aged 71, of cerebral hemorrhage.

Cartmell, Theodore Mithoff, Los Angeles; Columbia University College of Physicians and Surgeons, New York City, 1907; an associate member of the American Medical Association; veteran of World War I; served on the staff of the Hospital of the Good Samaritan; died July 3, aged 76, of congestive heart failure and arteriosclerosis.

Cavanaugh, Donald Nicholas ⊕ Wyoming, Ohio; Eclectic Medical College, Cincinnati, 1923; member of the American Academy of General Practice; associated with the Maple Knoll Hospital and the Good Samaritan Hospital in Cincinnati, where he died July 17, aged 58, of coronary thrombosis.

Cohen, Willi, New York City; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1905; died in the Beekman-Downtown Hospital May 21, aged 77.

Coleman, Clarence T. ⊕ Frankfort, Ky.; University of Louisville Medical Department, 1907; four-time mayor of Frankfort; in 1953, on his 71st birthday, was honored with a celebration of "Doctor Coleman's Day" by the people of Franklin County; associated with the Kings Daughters Hospital, where he died July 9, aged 75, of cerebral hemorrhage.

Cone, Andrew E., Portland, Ark.; Louisville (Ky.) Medical College, 1898; died in Dermott June 26, aged 81.

Crossley, Samuel Wallace ⊕ Lake Charles, La.; University of Texas School of Medicine, Galveston, 1919; member of the Texas Medical Association; died July 5, aged 75.

Counts, Noah Tilden, Cocoa, Fla.; University College of Medicine, Richmond, Va., 1907; an associate member of the American Medical Association; served on the staff of the Wuesthoff Memorial Hospital, Rockledge, where he died June 24, aged 81, of coronary occlusion.

Courter, Willard Orville ⊕ Bend, Ore.; State University of Iowa College of Medicine, Iowa City, 1938; a member of the district school board of Bend; veteran of World War II; past-president of the Central Oregon Medical Society; past-president of the medical staff of St. Charles Memorial Hospital; died July 14, aged 43.

Daniel, Joseph S., Corsicana, Texas; University of the South Medical Department, Sewanee, Tenn., 1895; died June 24, aged 89.

Davis, Warren Maynard ⊕ Bridgeport, W. Va.; Medical College of Virginia, Richmond, 1905; died July 26, aged 78.

de Brun, Harry Carl W. Schultz ⊕ New York City; Fordham University School of Medicine, New York City, 1915; professor of surgery at the New York Polyclinic Medical School and Hospital; fellow of the American College of Surgeons; for many years surgeon for the police department; associated with Lenox Hill and Reconstruction hospitals; died in Saranac Lake, N. Y., July 16, aged 67.

DeFeo, Amadeo Joseph ⊕ Everett, Mass.; Middlesex University School of Medicine, Waltham, 1937; died in York Beach, Maine, July 5, aged 47.

DeWitt, Charles H. ⊕ Valparaiso, Ind.; Chicago College of Medicine and Surgery, 1914; served as city and county health officer; examiner for the Selective Service; associated with the Porter Memorial Hospital, where he died June 22, aged 83, of arteriosclerotic heart disease.

Dempsey, Robert Bowne, Vallejo, Calif.; College of Physicians and Surgeons of San Francisco, 1903; an associate member of the American Medical Association; past-president of the Vallejo Chamber of Commerce; veteran of World War I; died July 9, aged 81.

Deskins, J. Tilden, Elkhorn City, Ky.; Kentucky University Medical Department, Louisville, 1905; died in the Methodist Hospital, Pikeville, July 12, aged 74.

Dooley, Frank Maxwell, Jackson, Miss.; Memphis (Tenn.) Hospital Medical College, 1890; died in the Mississippi Baptist Hospital June 29, aged 88.

Doolittle, George Miles, Portsmouth, Ohio; University of Buffalo School of Medicine, 1929; service member of the American Medical Association; formerly associated with the Veterans Administration Hospital in Fort Lyon, Colo.; on the staff of the Portsmouth Receiving Hospital; died July 13, aged 61.

Doyle, Helen MacKnight, San Francisco; Medical Department of the University of California, San Francisco, 1894; died in St. Francis Hospital July 22, aged 83, of arteriosclerotic heart disease.

Draper, Walter E., Billings, Mont.; Sioux City (Iowa) College of Medicine, 1904; veteran of World War I; died July 3, aged 76, of congestive heart disease.

Eder, Howard Leslie ⊕ Santa Barbara, Calif.; University of Minnesota Medical School, Minneapolis, 1922; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; at one time on the faculty of the University of Minnesota Medical School in Minneapolis; on the staffs of the Santa Barbara Cottage, Santa Barbara General, and St. Francis hospitals; died July 12, aged 60, of bronchial carcinoma.

Edmundson, Susan Offutt, Clearwater, Fla.; University of Pittsburgh School of Medicine, 1919; formerly practiced in Pittsburgh, where she was associated with St. Francis, Magee, and Shadyside hospitals; served on the staff of the Mayo Clinic, Rochester, Minn.; died July 15, aged 65, of coronary sclerosis.

Faver, Henry Merrell, Tampa, Fla.; Atlanta School of Medicine, 1909; served on the staff of the Tampa General Hospital; died July 7, aged 76, of myocardial infarction.

Fischl, Jacques Ruderfer ⊕ New York City; New York University College of Medicine, New York City, 1939; specialist certified by the American Board of Internal Medicine; served on the faculty of his alma.mater; chief physician of the New York Yankees baseball team; on the staff of the Lenox Hill Hospital; died in Le Touquet, France, July 24, aged 43, of pulmonary edema and coronary sclerosis.

Fleming, Patrick Joseph ⊕ Cambridge, Mass.; Tufts College Medical School, Boston, 1903; for many years city physician; died in the Cambridge City Hospital July 14, aged 81, of arteriosclerotic heart disease.

Flentje, Robert ⊕ Springfield, Ill.; St. Louis University School of Medicine, 1906; past-president of the Sangamon County Medical Society; died in St. John's Hospital July 16, aged 76.

Gaume, Harry W., Wichita, Kan.; Ensworth Medical College, St. Joseph, Mo., 1907; died July 15, aged 82, of cardiorenal disease.

Gilbert, Robert Samuel ⊕ New York City; Université de Genève Faculté de Médecine, Switzerland, 1949; died in the Mount Sinai Hospital June 25, aged 49.

Grala, William Leon, Hazleton, Pa.; Temple University School of Medicine, Philadelphia, 1919; an associate member of the American Medical Association and the Industrial Medical Association; on the staffs of the Hazleton State and St. Joseph's hospitals; served as director of the People's Savings and Trust Company; died July 19, aged 68.

Gulick, Arthur Cornelius ⊕ Goodland, Kan.; Jefferson Medical College of Philadelphia, 1900; served as county coroner and county health officer; on the staff of the Boothroy Memorial Hospital; died July 4, aged 87, of acute congestive cardiac failure.

Hardy, Hugh Winfred, Jasper, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1909; founder of the Hardy-Hancock Hospital; died in the John Sealy Hospital, Galveston, July 14, aged 70, of lower nephron nephrosis.

Harris, Grove Walton ⊕ Marshalltown, Iowa; St. Louis University School of Medicine, 1904; died in St. Mary's Hospital, Rochester, Minn., July 17, aged 74, of coronary occlusion.

Harsha, Gene Melford ⊕ Sistersville, W. Va.; University of Maryland School of Medicine and Colleg of Physicians and Surgeons, Baltimore, 1930; veteran of World War II; died July 22, aged 51, o sprue.

Hartenstein, Albert G., Rockland, Ohio; Universit of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1919; died in St. Joseph Hospital, Parkersburg, W. Va., June 24, aged 82, of cerebral hemorrhage.

Hartwell, John Bryant ⊕ Colorado Springs, Colo.; Harvard Medical School, Boston, 1904; formerly on the faculty of his alma mater; in 1939 vice-president of the Colorado State Medical Society; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; served on the staffs of the Memorial and St. Francis hospitals, and the Glockner-Penrose Hospital, where he died July 15, aged 78, of cerebral arteriosclerosis.

Hayes, Maurice Augustine, Cambridge, Mass.; Kansas City University of Physicians and Surgeons, Kansas City Mo., 1922; veteran of World War I; died in the Veterans Administration Hospital, Boston, June 19, aged 64.

Hazeltine, Harry Hobart, Everett, Wash.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; also a graduate in pharmacy; died July 5, aged 85, of heart disease.

Helwig, Edward C., Indianapolis; Indiana University School of Medicine, Indianapolis, 1908; veteran of World War I; for many years associated with the Veterans Administration; died July 1, aged 72, of arteriosclerotic heart disease.

Hewitt, Leland Victor ⊕ Detroit; University of Michigan Medical School, Ann Arbor, 1923; on the staff of the Grace Hospital; died July 6, aged 58, of coronary occlusion.

Hiller, John P., Pollard, Ark.; St. Louis College of Physicians and Surgeons, 1903; died in the Piggott (Ark.) Hospital July 7, aged 80, of cerebral hemorrhage.

Hoffer, James Jacob, Chicago; National Medical University, Chicago, 1907; also a dentist; died in Long Island, N. Y., July 15, aged 79, of a heart block.

Jastram, Alfred Henry, Remsen, Iowa; Sioux City (Iowa) College of Medicine, 1897; served on the faculty of his alma mater; for 20 years chairman of the board of education; member and past-president of the county board of education; past-president of the staff of Sacred Heart Hospital in Le Mars; local surgeon for the Illinois Central Railway for 50 years; died July 8, aged 85, of arteriosclerotic heart disease.

Joyce, Edward, Hurley, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; an associate member of the American Medical Association; past-president and vice-president of the Yankton District Medical Society; served as a member of the city council and as mayor; vice-president of the Hurley State Bank; died July 4, aged 77, of cerebral hemorrhage.

Kallenberg, Henry Frederick, River Forest, Ill.; Northwestern University Medical School, Chicago, 1900; died at the YMCA Camp near Estes Park, Colo., where he was recreation director, July 25, aged 91.

Kendall, Eugene Lurell ⊕ Grand Rapids, Mich.; Detroit College of Medicine, 1909; died July 9, aged 79, of bronchopneumonia and cerebral thrombosis.

Kinnaman, Clarence Horace ⊕ Topeka, Kan.; Keokuk (Iowa) Medical College, 1899; served as state epidemiologist for the Kansas State Board of Health; veteran of World War I; at one time health officer of Geary County; member of the American Public Health Association and the Kansas Public Health Association; died in the Veterans Administration Hospital July 9, aged 88, of bronchopneumonia.

Knott, Howard James ⊕ Seattle; Johns Hopkins University School of Medicine, Baltimore, 1911; fellow of the American College of Surgeons; veteran of World War I; on the staff of the Seattle General Hospital; served as overseer and trustee at Whitman College, where in 1954 he was awarded the honorary degree of doctor of science; died July 7, aged 78, of coronary thrombosis.

Kunz, York, Rochester, N. Y.; Friedrich-Wilhelms Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1908; veteran of World War I; for many years on the staff of the Monroe County Hospital; died July 16, aged 74, of cerebral vascular accident.

Leopold, Francis D. ⊕ Buffalo; University of Buffalo School of Medicine, 1914; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served on the faculty of his alma mater; past-president of the Buffalo Academy of Medicine; on the staff of the Buffalo General Hospital, where he died July 8, aged 69, of hypertension.

Lewin, Norbert, New York City; Martin Luther Universität Medizinische Fakultät, Halle-Wittenberg, Prussia, Germany, 1922; died July 4, aged 61.

Lewis, Claud, St. Cloud, Minn.; Washington University School of Medicine, St. Louis, 1924, service member of the American Medical Association; member of the American Psychiatric Association; veteran of World Wars I and II; associated with the Veterans Administration Hospital; died June 27, aged 59.

Loomis, Ralph Henry ⊕ Sidney, N. Y.; Syracuse University College of Medicine, 1909; served overseas during World War I; formerly member of the board of education and county coroner; received Sidney's highest honor in 1946 when he was named "Man of the Year"; for many years chief of the staff, The Hospital, where he died July 6, aged 71, of coronary occlusion.

Mahoney, John Francis ⊕ New Bedford, Mass.; Tufts College Medical School, Boston, 1915; died in the Veterans Administration Hospital May 17, aged 65, of arteriosclerosis.

Morse, Samuel, New York City; University and Bellevue Hospital Medical College, New York City, 1906; specialist certified by the American Board of Ophthalmology; served as instructor in ophthalmology at the New York Post-Graduate Medical School and Hospital; on the staff of the Fordham Hospital; died July 5, aged 70, of cerebral hemorrhage.

Schneider, Carl Oscar ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; died in the Grant Hospital July 18, aged 78, of myocardial infarction.

BRAZIL

Electroencephalographic Findings in Cerebral Abscess.—In *Arquivos de Neuro-psiquiatria* (June, 1957) P. P. Pupo and co-workers called attention to the electroencephalographic findings in patients with cerebral abscess. In a series of 22 patients, 20 had electroencephalograms prior to operation and 2 had postoperative electroencephalograms only; 17 of the 20 also had postoperative tracings. All patients were operated on, and all received antibiotics. In the group of patients who had a preoperative electroencephalogram, the authors invariably found diffuse changes in the tracings. They found focal changes consisting mainly of delta waves of 0.5 to 3.0 cycles per second with a potential of 400 to 500 mv. in 19, focal depression of the basic rhythm in 11, and an epileptogenic focus in only 2. Slow delta waves and focal depression of the basic rhythm are diagnostically important, particularly when studied in relation to the clinical findings.

In those who had clinical and electroencephalographic examinations 1 to 60 months postoperatively, the authors found an active convulsive focus in 10 of the 17 patients. This incidence is high, and it is in accordance with the high frequency of epilepsy after cerebral abscess. The period between the operation and the onset of the focal activity varied from 1 to 25 months. Of the 10 patients with focal activity and clinical epilepsy, only 2 showed focal activity before the healing of the abscess. The authors believe that the healing, which is a gradual process, is responsible for the onset of these clinical and electroencephalographic manifestations. In the same group, only four patients had normal electroencephalograms during the follow-up; two had normal electroencephalograms during 5 and 15 months, respectively, but showed focal activity later. Three other patients had signs of nervous tissue damage (delta waves) one to three months after the operation (patients with convulsive seizures or with signs of a developing abscess). In six patients there were slight changes of the basic rhythm due to the healing and with no clinical correlation. The authors concluded that the electroencephalogram is an important auxiliary in the diagnosis of cerebral abscess and in the prognosis of patients who are surgically treated, since in the latter it may reveal disappearance of acute signs of cerebral involvement or early formation of an active convulsive focus, permitting the institution of the anticonvulsive therapy.

Acute Leukemia.—Seventeen patients (12 children and 5 adults) with acute leukemia were given 1 Gm. of prednisone daily by Dr. Michel Abujamra and co-workers (*Revista do Hospital das Clínicas de São Paulo*, June, 1957). The criteria used for evaluation of the results were those of the Cancer Chemotherapy National Service Center of the United States. The mean duration of complete remission was 64 days, and the maximum was 210 days. The mean survival time was 165 days, and the maximum was 450 days. The steroid has specific action on the leukemic cells, stimulating the erythropoiesis, the granulopoiesis, and the platelet production. No toxic effects were registered, even in the electrolyte serum concentration. The authors concluded that prednisone is a valuable therapeutic agent in spite of its temporary action. The large doses used by them gave longer remissions and survival times than did the usual doses of about 2.2 mg. per kilogram of body weight. Prednisone seems to be indicated, especially in large doses, in the severe acute cases in which there is no time to wait for the gradual response to such agents as mercaptopurine and the folic acid antagonists.

Fulminating Necrotic Colitis.—Five cases of fulminating necrotic colitis after antibiotic therapy were reported at a meeting of the Medical Society of Ribeirão Preto by Estevão Nador and L. H. Camera Lopes. All the patients died postoperatively of toxemia. Although not previously observed in Brazil, many such cases have been reported from other countries. The condition is attributed to the development of strains of micrococci, enterococci, Pseudomonas aeruginosa, and other bacteria resistant to antibiotics, particularly those of wide range of action. The patients complain of profuse and bloody diarrhea, vomiting, and high fever. Dehydration and toxemia lead to irreversible shock. Autopsy reveals necrosis of the colon. The lesions were pseudomembranous, pseudopolypous, and fibrinonecrotic. Microscopically, the main alterations seen were necrosis of the mucosa, lymphocytic infiltration of the lamina propria, and thrombosis of the blood vessels.

The items in these letters are contributed by regular correspondents in the various foreign countries.

INDIA

Infant Feeding.—P. T. Rao (*Indian Journal of Child Health,* July, 1957) analyzed the nutritional habits and status of 2,100 children attending the outpatient department of the Government General Hospital in Madras. Of these, 1,826 (83.9%) were under the age of 5 years. All had been breast fed up to one year of age, 79% had been breast fed up to the age of 18 months, and about 59% had been breast fed at the age of 2 years. The earliest supplemental feeding given to infants of the lower economic group is coffee, given even as early as 6 months of age. Such nutritive food supplements as milk and other protein foods are given to 41% of children under the age of one year and to 30% between 1 to 5 years of age. Even so cheap a carbohydrate supplement as rice is usually not given until the infant is one year old. The incidence of vitamin A deficiency, which was taken as an index of nutritional status, was maximal among children receiving only breast milk after the age of 12 to 18 months, with a steep rise in incidence after 18 months. These children who were breast fed for prolonged periods were not given adequate vitamins or calories as evidenced by their deficiency of vitamin A. Those children who received supplementary milk in addition to breast feedings were found to be in better health than those who were given only breast milk or had such supplementary foods as coffee and rice. More cow's milk in the diet of these children would alleviate many of the problems of child health.

Water Tolerance Test.—A. Ahmed (*J. Indian M.A.* 29:3 [Aug.] 1957) noted that retention of salt and water is a complication of many types of chronic illness and leads to edema in chronic anemia and hypoproteinemia. In health, sudden ingestion of a large amount of water leads to an immediate response from the kidney with elimination of the excess water and some salt within a few hours. In chronic illness, this response is altered. The author studied the ability of kidneys to eliminate water and chlorides when the water content of the body is increased by the ingestion one liter of water. Healthy subjects eliminated an average of 908 cc. and the diseased subjects an average of 766 cc. of urine within three hours. The pattern of diuresis was almost the same in health and chronic disease, the peak diuresis occurring at 90 minutes in both groups, though the average maximal flow of urine per minute was only 6 cc. in the diseased group.

In most patients, tolerance to a test dose of water was not abnormal. With this test dose of water, the average healthy subject eliminated, within three hours. an average of 1.7 Gm. of chlorides as sodium chloride, and ill subjects eliminated 1.75 Gm. An intake of water up to 5 or 6 liters in 24 hours results in the elimination of more chlorides, with additional elimination of water leading to a state of dehydration. No correlation was noted between the hemoglobin or the total plasma protein concentration of blood and the maximal flow of urine per minute or total output of urine in three hours after ingestion of the test dose. Aminophylline was effective in increasing the urinary excretion of water and chlorides. The administration of aminophylline and ammonium chloride helps in sustaining the diuretic effect of mersalyl sodium for several days and also potentiates its diuretic activity.

NORWAY

The Prosodic Grunt.—G. H. Monrad-Krohn (*Journal of Mental Science,* vol. 103, no. 431, April, 1957) considers prosody the third fundamental element of speech, the first and second being vocabulary and grammar. As an example of the author's use of the term, he cites the case of a young woman whose traumatic lesion of the left cerebral hemisphere left her with a pecularly changed language, the salient feature of which was such a complete change of her "melody of speech" that she was taken for a foreigner. The prosodic grunts which she had lost are an important part of everybody's speech pattern. When we listen to a person, we betray our interest, assent, or dissent by interjections or short words such as oh, quite, and perhaps, or probably more often by inarticulate sounds, the tone of which expresses our sentiments. You are a good or a bad listener according to whether your mastery of prosodic grunts is good or bad. A patient with paralysis agitans often loses these prosodic grunts completely. The son of such a patient may conclude that "father is not so bright as he was, he no longer takes the same keen interest as before, nor does he seem to grasp the points." Bereft of prosodic grunts, father is put down as being "cold and unfeeling." He begins to get isolated, he feels resentful about the altered mental atmosphere, becomes depressed and even hostile to his surroundings, and a vicious circle is set up, all for want of a quality in speech which we do not appreciate till we have lost it.

Thoracoplasty.—Dr. Alexander Tuxen has incorporated his long experience of pulmonary tuberculosis in a monograph entitled "A Study of the Course of Pulmonary Tuberculosis After Treatment with Thoracoplasty" (Oslo University Press). A series of 977 patients formed the basis for this study. The minimum observation period was five years. This study does not lend itself to any facile summing up of the author's conclusions, but as a work of reference it should be of special value to the physician who wants to know what can be achieved by thoracoplasty and what are the chief conditions likely to determine the outcome of this operation in any given case.

SWITZERLAND

Afibrinogenemia.—Until recently the danger of transmission of hepatitis by fibrinogen was an unsolved problem. Since the efficiency of ultraviolet irradiation is doubtful, it seems desirable to keep the plasma pools from which fibrinogen is to be prepared as small as possible. In Berne, the plasma from only two donations is united in ordinary blood bottles. Precipitation of fibrinogen with alcohol, centrifugation, resolution of the precipitate, and lyophilization are subsequently carried out under sterile conditions in the same bottle (*Vox Sanguinis* 2:100, 1957). The tedious and yield-lowering filtrations are omitted. Fibrinogen from two blood donations contains on the average 1 Gm. of clottable fibrinogen. This preparation is distributed by the Red Cross Blood Transfusion Service to maternity wards for emergency treatment of acute afibrinogenemia. Fibrinogen has also proved its hemostatic activity in cases of thrombopenic bleeding.

UNITED KINGDOM

New Hypoglycemic Drugs.—At the meeting of the British Diabetic Association at Oxford, a series of papers was read on the use of the sulfonylureas in the treatment of diabetes mellitus. Dr. R. F. Mahler reported that more sustained plasma concentrations were obtained with carbutamide than with tolbutamide. The latter produced higher plasma levels four hours after administration, but rapid excretion subsequently resulted in failure to maintain active therapeutic concentrations for 24 hours. Dr. Joyce Baird, of Edinburgh, confirmed these findings and said that, although a single daily dose of carbutamide could maintain control, tolbutamide should be given in two equal doses. In most patients, two doses of 0.5 to 1.5 Gm. in 24 hours were adequate, but a few required three or even four doses. In Dr. Baird's experience, plasma concentrations of 8 to 18 mg. per 100 ml. were the most satisfactory therapeutically. Most workers appear to have abandoned carbutamide in favor of tolbutamide therapy on account of the toxic effects of the former. Sustained control is achieved by the use of tolbutamide in 36 to 55% of patients considered likely to respond to oral therapy on clinical grounds—those with milder forms of diabetes, usually over 45 years of age, and not likely to become ketotic. Some patients appear to become refractory to the drug. There appears to be no way of determining which of the apparently suitable patients will respond, apart from clinical trial. In 2 of 155 patients treated with tolbutamide, thrombocytopenia and leukopenia developed but not to a serious degree. About 25% of the patients taking 40 units or less of insulin a day could be well controlled if tolbutamide were substituted for insulin.

In his series of 72 patients, Dr. J. D. N. Nabarro found a long-term satisfactory response in 31 (43%). In an outpatient trial, involving 142 patients, Dr. M. Dulake reported satisfactory control in 36%. Dr. Arnold Bloom reported that after a six weeks' course of 2 Gm. of tolbutamide daily, 22 of 32 patients who had responded remained controlled adequately on withdrawal of the drug. Dr. Ian Wang of Glasgow reported that of 100 patients given a 14-day course of 1 Gm. of tolbutamide daily, 57 responded satisfactorily. Of these, 22 remained controlled without further therapy. Of those who relapsed afte varying periods, 22 responded to a further course o the drug.

Influenza A Virus.—During the winter of 1955-195 in England and Wales, 101 strains of influenza virus were isolated by laboratories of the Publ Health Laboratory Service, according to L. A. Hatc (*Month. Bull. Min. Health* 16:138, 1957). Hema glutination-inhibition tests with each strain, usi ferret serums, showed that 97 strains resembled the Scandinavian 1953 group, two resembled the Eire 1955 group, and two resembled the Dutch 1956 group. The Eire 1955 and Dutch 1956 strains showed a marked difference serologically from each other and from Scandinavian 1953 strains. The analysis of the 97 available Scandinavian strains showed that, whereas they resembled each other as a group, there was much variation within the group, particularly in the degree with which individual strains reacted with strain-specific serums.

Medical Aspects of the Suez Campaign.—The first report of the medical aspects of the Suez campaign is published in *The Practitioner* (179:191 [Aug.] 1957). It is by three physicians who were members of the first field ambulance to be ashore—10 minutes after the assault began on Nov. 6. The first casualties were dealt with on the beaches, but, within an hour, headquarters had been set up in a battered hotel, while sniping still went on in the cellars and gardens. On the first day, this company treated 70 British casualties within the framework of the policy of urgent evacuation. At first, helicopters were flying in commandos from the aircraft carriers lying offshore, and casualties were loaded into them for the return flight. All operations at this stage took place on the carriers. No British wounded were held for longer than 30 minutes. Later in the day, the ballroom of the hotel was cleared of its wreckage and used as a ward; the kitchen became a mortuary and a bar the operating room. By this time the company had been joined by a field surgical team. By noon on Nov. 7, they had 50 seriously wounded Egyptians. The casualties were both military and civilian, but at times it was difficult to distinguish them. Some were naked, and these were known to be military, as many had discarded their uniforms in the belief that this would prevent reprisals. Some civilians, when searched, were found to be armed. A 12-year-old boy was armed with a Czechoslovakian automatic carbine. Those who could speak English protested their love for the British, but these usually were found to be the most heavily armed.

Senior and specialized medical officers visited the Egyptian hospital, and the hospital was supplied with such drugs, dressings, and blood as could be spared. A civilian Egyptian surgeon, with whom the unit had the most cordial professional relations, stayed in the hospital for some time and went round the improvised ward. The major lesson of the campaign was that the helicopter as a means of evacuation (from battlefield to hospital bed in 30 minutes) is a great lifesaving factor for battle casualties, reducing shock to the minimum and providing the security for which the wounded crave. Without this method of evacuation, many of these severely wounded men would not have reached the operating table alive.

Shellfish Regulations.—Most of the 7,000 tons of cockles eaten annually are cooked by the producers before distribution. In spite of the fact that, under the shellfish regulations of 1934, the heat treatment specified is sterilization by steam under undefined pressure, many of the cockles on the market are still heated in open cauldrons for about four minutes. Cockles cooked thus and salted for distribution are preferred by some to steamed cockles, which are said to lose their flavor. Further, the cost of installing an apparatus for steaming, at the moment, would be prohibitive and would put many fishermen out of business. H. P. Sherwood (*Month. Bull. Min. Health* 16:80, 1957) therefore determined the conditions under which immersion in hot water could be relied on to sterilize shellfish in respect to bacteria of the coli-aerogenes group. His experiments on heating shellfish in a relatively large volume of water, to prevent cooling of the water on immersion, showed that sterilization of large cockles and mussels resulted from immersion for two and two and one-half minutes, respectively, at 100 C. For each reduction of water temperature by 10 C down to 70 C, extension of the immersion period by about half a minute was necessary. It is therefore suggested that to make polluted cockles and mussels safe for human consumption by heating in bulk, they should be kept fully immersed in boiling water for one and two minutes, respectively, after resumption of boiling.

Nial Reynolds (*Month. Bull. Min. Health* 16:86, 1957) reported that, at 100 C, one to one and one-half minutes' cooking is necessary before the flesh of periwinkles can readily be removed, though cooking for one-half minute is sufficient to destroy any coliform bacteria present. At 70 C, cooking for one minute was necessary to destroy such bacteria. Cooking which was sufficient to render the flesh extractable was sufficient to disinfect the periwinkles. In other words, if a periwinkle has been cooked sufficiently to be eaten by the traditional pin method, any enteric bacteria derived from pollution of the periwinkle beds will have been destroyed.

Penicillin Resistance in Cattle.—In a two-year period (1954-1956), the incidence in Dorset of penicillin-resistant Micrococcus pyogenes var. aureus in herd milk samples increased from 9 to 37%, according to G. H. Tee (*Month. Bull. Min. Health* 16:141, 1957). Evidence is adduced that the use of penicillin in treating bovine mastitis—usually of micrococcic origin—is widespread, and it is suggested that this may be responsible for the emergence of the penicillin-resistant strains.

Inhibitor of Gastric Secretion.—Douthwaite and coworkers (*Brit. M. J.* 2:275, 1957) investigated the effect of a new parasympatholytic compound, (1-methyl-2-pyrrolidyl) methyl benzilate methyl methosulfate, or IS 499, on gastric secretion. Doses of 1 to 20 mg. given at 11 p.m. or 5 a.m. reduced the secretion of gastric acid in response to a test meal in the early morning. A dose of 5 mg. given three hours before the test reduced the gastric secretion of acid by 40 to 60%. Larger doses inhibited gastric secretion for nine hours. There were no troublesome side-effects with doses up to 10 mg. Clinical trials are being undertaken to see if IS 499 is suitable for the control of acid secretion in patients with duodenal ulcer.

Epidemic of Encephalomyelitis.—Between April, 1955, and January, 1956, a total of 60 patients with poliomyelitis were treated in the infectious diseases unit of the Royal Free Hospital, London. In the same period, 15 patients were observed in whom the diagnosis was acute encephalomyelitis, details of which are given by A. Melvin Ramsay (*Pub. Health* 71:98, 1957). Motor weakness, rigidity, exaggerated reflexes without muscular wasting, sensory disturbances, and normal spinal fluid findings suggested a disease other than poliomyelitis. This was confirmed by negative serologic tests for all three types of poliomyelitis virus. Electromyography revealed absence of the denervation characteristic of poliomyelitis and the presence of long polyphasic units with reduced interference pattern characteristic of a myelopathic lesion. The occurrence of reticuloendothelial hyperplasia in some patterns suggested that there may be a viremic phase, after which the disease may abort. Five patients with behavior changes were examined by electroencephalography. Abnormalities were detected in all five, but these were nonspecific and might well have been constitutional and not due to infection. The pattern of the disease was similar to that observed in outbreaks which have occurred in Iceland, the United States, Australia, and South Africa. This is believed to be a new disease.

Embassy's Doctors.—An advertisement in the medical press for a medical officer for the British Embassy in Moscow specified that he be under 40 and, if married, preferably have not more than one child. A correspondent in *The Lancet*, protesting against such a condition, wrote: "This encouragement of only children, with all its disadvantages both to child and parents, is unworthy of the employer and is, in addition, a very poor exemplification of the British way of life in an important setting—Moscow."

Fibrocystic Disease of the Pancreas.—Fibrocystic disease of the pancreas is being recognized with increasing frequency. Estimation of the concentration of sweat electrolytes is considered the most reliable of the many laboratory tests used, but the dangers associated with causing infants wrapped in plastic bags to sweat has prompted the devising of alternative methods. MacFarlane and co-workers (*Brit. M. J.* 2:274, 1957) use a medium prepared by adding 4.2 Gm. of silver nitrate and 2.4 Gm. of potassium chromate to 500 ml. of normal agar base. When this is applied to the finger tips, the salt in the sweat decolorizes the orange silver chromate suspended in the agar. An estimate of the salt content of the sweat can be made from the degree of decolorization in unit time. To date 53 patients with known fibrocystic disease have been tested by this method, and all gave a strongly positive sweat reaction for sodium chloride. This test offers a simple and reliable method of screening cases of suspected fibrocystic disease.

New Method for Estimating Blood Glucose Levels.—It is well known that the estimation of blood glucose levels by reducing methods lacks specificity and gives values that are too high. Huggett and Nixon (*Lancet* 2:368, 1957) describe a new and highly specific method. In the presence of glucose oxidase, which is highly specific for glucose, the latter is oxidized to gluconic acid and hydrogen peroxide. This, in the presence of peroxidase, can oxidize a suitable oxygen acceptor to give a colored oxidation product, the intensity of color being proportional to the amount of glucose present. Glucose oxidase is obtainable from Penicillium notatum and peroxidase from horseradish. The oxygen acceptor used is o-dianisidine, dissolved in 95% alcohol. A mixture of these substances adjusted to a pH of 7 gives an orange-brown color in the presence of glucose. The blood glucose level is estimated by adding to the blood an anticoagulant (heparin, or a mixture of sodium fluoride and potassium oxalate), deproteinizing with alcohol or zinc hydroxide, and incubating the filtrate at 35 to 37 C for one hour with the mixture of glucose oxidase, peroxidase, and o-dianisidine. The color that develops is compared in an absorptiometer or spectrophotometer with the colors produced by standard glucose solutions. The glucose level may be estimated in plasma directly, if allowance is made for its color in a blank, but, for the estimation of glucose in urine, the latter must first be decolorized with charcoal.

Guy's Hospital.—The Ministry of Health has approved the rebuilding of Guy's Hospital, one of the better known London teaching hospitals, founded in 1721 by Thomas Guy, a London bookseller and philanthropist. The hospital suffered extensive bomb damage during the war. A start will be made in September on the erection of a new surgical block costing $5,600,000 on the site of a wing demolished by bombing. It will have nearly 400 surgical beds, 10 operating theaters, and new casualty and radiotherapy departments. The major part of the cost will be borne by the Ministry of Health, although Guy's Hospital itself will contribute a substantial sum from its own funds, and the University Grants Committee will make a grant. The rebuilding plan includes a new medical school. Much of the present building dates back to the original hospital of 1721. Additions were made in 1851, and, because of its historic associations, part of the old hospital will be preserved.

U. S. Servicemen to Be Vaccinated Against Asian Influenza.—The Asian influenza epidemic has reached some of the United States Air Force camps in Great Britain. The areas affected are at Newbury, Burtonwood, and West Drayton. Vaccination of 80,000 members of United States armed forces in Britain will begin in October with vaccine imported from the United States. Although extensive field trials of the Asian influenza vaccine made at the Wright-Fleming Institute, St. Mary's Hospital, London, have been planned, no preparations for large-scale vaccination of the British population have been made. Sporadic outbreaks are occurring in schools and armed forces barracks. It is reported that the infection is spreading rapidly in Lagos, Nigeria, where the number of cases has reached 3,500. The mortality there is low. Four physicians and 50 hospital personnel of the General Hospital suffered from Asian influenza, which is seriously affecting many commercial organizations. The epidemic started in Kano, Northern Nigeria, where more than 3,000 cases were reported.

Contaminated Beaches.—It will be two or three years before a final report is available on whether sewage-polluted sea water is harmful to bathers. An investigation started two years ago will take time to complete, according to Dr. G. S. Wilson, director of the Public Health Laboratory Service. The service began the inquiry on its own initiative to determine whether any serious effects are apparent in human beings as a result of discharge of untreated sewage into the sea. Sometimes bathing beaches were condemned unnecessarily, and sometimes beaches which should have been marked as contaminated were open to the public. A prodigious degree of contamination due to sewage exists around Great Britain's coasts. Along the south coast an estimated 40 gallons of sewage-contaminated water are poured into the sea per person per day. This is supplemented by discharge from ships. The contamination of other seaside areas is of about the same order.

Renewed attention is being given to the problem this year because of the increased incidence of unexplained poliomyelitis. The Minister of Health has said there is no evidence of transmission of poliomyelitis or any other disease through sewage-infected sea water. Though agreeing, many experts regard this as a negative approach, stating that there is also no evidence that poliomyelitis and other diseases are not so transmitted. Mr. A. Sciver, president of the Institution of Public Engineers, said that the danger had increased markedly in recent years. Holidays with pay have resulted in many more families visiting the coast each summer. Samples of water taken at intervals along the south coast showed that for several miles out to sea the water was not fit for bathing "by fresh water standards." It might be that sporadic cases of poliomyelitis occurring inland are due to infection of people who bathed at seaside resorts in contaminated water. From an aircraft, Mr. Sciver was able to study a 10-mile belt of opalescent polluted water stretching from the south coast. This area moved back and forth with the tide, only the periphery gradually diffusing into the greater volume of sea water. Gulls which scavenged on the discharged effluent had an unfortunate habit of then spending the night on local reservoirs. Where sewage percolated over a beach, rock pools where children played were contaminated.

Every estuary in the country is more or less contaminated. London pours 350 million gallons of crude sewage into the tidal Thames every day. Because of the "piston" effect of the tides it might take eight days to clear one discharge to sea. Shellfish are contaminated and may cause outbreaks of dysentery or typhoid if eaten raw or after inadequate cooking. Whatever the results of investigation into the health hazards, reports from wide areas of the coast leave no doubt that beaches are too often unpleasantly encrusted. Many inhabitants will not bathe or permit their children to bathe in these areas, but visitors frequently are ignorant of the proximity of sewage outfalls. At Gosport, a notice warning tourists not to bathe was removed because it curtailed tourist trade. Few local authorities regard it obligatory to give warnings of contamination of their beaches. At Bournemouth, where a public health service laboratory is conducting an inquiry, the resort's stretches of golden sand, though pleasing from a distance, are often distasteful at close range.

An annotation in the *British Medical Journal* of Aug. 17 states that a patient with poliomyelitis may excrete in 1 Gm. of feces enough virus to infect one million monkeys. Half the patients are still excreting virus after 3 weeks, and some continue to excrete it up to 12 weeks. Since many rivers, streams, and ditches in Great Britain, as in other countries, are polluted by human excreta, parents should keep their children away from such area when cases of poliomyelitis are occurring in them. If sewage containing poliomyelitis virus is pumped into the sea and it comes into contact with bathers, there would seem to be some risk of the disease being transmitted. Since no outbreak of poliomyelitis has been traced to this particular source, the risk of infection is probably slight, but while coastal resorts continue to grow and more and more people take seaside holidays, England is fast becoming a jewel set in a sea not of silver but of sewage.

Poliomyelitis Risk to Family Physicians.—Whether general practitioners and their families in areas where poliomyelitis is rife should be vaccinated is to be considered by the Joint Committee on Poliomyelitis Vaccine. There is evidence that family physicians run special risks. Doll and Hill, of the Medical Research Council, reported earlier this year that between 1951 and 1956 there were eight deaths from poliomyelitis among 34,494 physicians in Great Britain. According to the rate in the general population, not more than one such death would have been expected.

CORRESPONDENCE

PHENYLKETONURIA

To the Editor:—Recently there has been some unsolicited publicity in the lay literature about a project which the College of Medical Evangelists is undertaking. The project is concerned with the possibility of detecting cases of phenylketonuria in early infancy by means of a simple diaper test. Detection of these cases has become of importance due to the recent studies which show that mental deficiency may be prevented if treatment is instituted early. The Los Angeles City, the Los Angeles County, and the San Bernadino County health departments are cooperating with us by allowing the testing to be done on the many thousands of infants in their well-baby clinics (a total of well over 600 "half-day" clinics per month). It is estimated that in the neighborhood of 125,000 tests will be performed on 35,000 to 45,000 infants per year. This letter is to acquaint other doctors with the test that is being done.

Phenylketonuria has been described as medicine's first foothold in the solution of the many unknown causes of mental deficiency. Before 1934 these patients were part of a large group of mental defectives due to unknown causes. In 1934, Folling demonstrated the abnormal excretion of phenylpyruvic acid in the urine. The condition proved to be a hereditary error of metabolism which is transmitted by a recessive gene. The babies are born normal and then progressively degenerate between about 4 months and 24 months of age to levels of severe to moderate mental deficiency. Frequently they have fairer skins and lighter hair than their parents and normal siblings. The error in phenylalanine metabolism has been extensively studied. The amino acid, phenylalanine, is present in every diet and is normally metabolized to tyrosine. In persons with phenylketonuria this pathway is blocked and phenylalanine accumulates in the blood and spills over in the urine as phenylpyruvic acid. The excess phenylalanine in the blood coincides with progressive mental deterioration.

Recent studies have shown that a phenylalanine-restricted diet if started early enough in infancy can prevent mental deficiency. Observations also suggest that the special diet may not be necessary beyond 2 or 3 years of age. Studies on institutionalized mental defectives (where phenylketonuria constitutes approximately 1% of cases) indicate that the incidence of this condition is about 1 in 25,000 in the general population. However, no survey of the general population has been reported yet. Detection efforts thus far have been confined largely to children already showing evidence of retardation and to siblings of persons known to have phenylketonuria.

The test is a simple adaptation of the standard urine test for phenylketonuria. We believe, and hope that it will be proved, that this simple and extremely inexpensive test should be a routine well-baby examination in the early months of life. The test consists of placing a drop of 10% solution of ferric chloride on a freshly wet diaper. A positive reaction is the almost immediate appearance of a dark blue-green color. (Bile is the only other substance we know of in urine that gives a green color with ferric chloride. Diacetic acid will give red-brown and aspirin blue-purple.)

The test is positive in affected infants from about 4 weeks of age on. It has been found that these children occasionally do not excrete phenylpyruvic acid and therefore the test should be repeated at each well-baby visit. Positive reactions can be verified by mixing equal amounts of urine and 2,4-dinitrophenylhydrazine in 1 *N* solution of hydrochloric acid. A yellow turbidity should occur within several minutes.

We have tried this diaper test in a number of known cases of phenylketonuria and find that it is reasonably dependable. We have now two young infants under our care who at the time of initial diagnosis, at 6 and 7 weeks of age respectively, had positive diaper tests (confirmed by other tests including blood phenylalanine levels). This has encouraged us, because prior to this we had no proof that the diaper test would work on such young infants. The spots were of a medium intensity grey-green color.

One last point, although we feel that the screening program as we have outlined it is perhaps new, we do not claim originality for the idea of using a drop of ferric chloride on a wet diaper. Several writers have suggested that such might be tried if urine samples were not available.

MEDICOLEGAL ABSTRACTS

Malpractice: Degree of Proof Required.—This was an action by a surviving husband to recover damages for the wrongful death of his wife, which resulted from the alleged negligence and malpractice of the defendant physician and the defendant hospital. From a judgment sustaining the defendants' separate demurrers to the plaintiff's evidence, the plaintiff appealed to the Supreme Court of Kansas.

The court's summary of the evidence indicated that several months after the plaintiff's wife became pregnant, she went to the defendant physician for treatment. She was the mother of three children and the defendant had been her doctor for each of her former pregnancies. During her last pregnancy, in connection with which her death resulted, there were no symptoms of anything unusual, and all signs pointed toward a normal childbirth with normal results. Early in the morning of Feb. 6, 1954, the plaintiff's wife had a discharge indicating the imminence of commencement of labor and notified the defendant by telephone. He directed her to go to the defendant hospital at once, which she did. He arrived at the hospital a few minutes after she did and his examination showed that she was not yet in labor but that early labor was anticipated. This was about 5:45 a.m. There was nothing to indicate anything wrong with her condition or that delivery would be anything other than normal. Later that morning the defendant directed some medication and that afternoon he made another personal examination. There being no signs of definite labor, he directed further medication. Shortly afterwards a few contractions commenced and at 3:30 p.m. the membranes ruptured normally. Thereafter the contractions increased to proper stage and medications were discontinued. At 10:45 that night the defendant again made a personal examination and directed medication. At 2 a.m. the next morning, obstetric nurses, who, in the meantime, had been caring for the plaintiff's wife in the regular course of their professional duties, advised the defendant that her progress was nearly complete. He arrived at the hospital a few minutes later, after which the fetus was delivered. Blood plasma and oxygen were administered but the patient died about an hour and a half later. An autopsy was performed by a recognized and experienced pathologist and this examination disclosed that the patient's death occurred as a result of hemorrhage due to a rupture of the uterus after delivery. The evidence further disclosed that the upper part of the uterus, instead of thinning out as the fetus developed, as is ordinarily the case, was more than twice the usual thickness, while the lower and smaller part of the uterus, where the rupture occurred, had developed extremely thin, and that such condition was latent and a very unusual type of abnormality, and that ordinarily there would be no warning of such condition prior to delivery.

With respect to the part played by the hospital and attending nurses, the evidence disclosed that there was nothing unusual or out of the ordinary in connection with the patient's pregnancy leading up to her actual delivery, and that during the period she was in the hospital she was under the routine and regular care of nurses of many years' experience, and that they ministered to her in the usual and ordinary manner in the light of her known condition. During this period she was given the usual and customary rectal examinations, and nurses assisted the doctor in the actual delivery, as was customary. Medical testimony was to the effect that at her state of pregnancy a vaginal examination would be improper and that only rectal examinations would be, and were, given.

The plaintiff testified he was in the delivery room a part of the time and that he observed what the nurses were doing with respect to making examinations, and he expressed the opinion that his wife was given a vaginal examination. He also testified concerning pressure applied by the nurses to his wife's abdomen. Finally there was testimony from several members of patient's family concerning a conversation had with the defendant the day following her death in which he was alleged to have said that perhaps her life could have been saved if a cesarean operation had been performed.

The Supreme Court said that the relationship between a physician and his patient, implied in law, is that he possesses that reasonable degree of learning and skill ordinarily possessed by members of his profession and of his school of medicine in the community where he practices or similar communities, having due regard for the advance in medical or surgical science at the time, and that he will use such learning and skill in his treatment of the patient with ordinary care and diligence. This rule is elementary and is founded on considerations of public policy, its purpose being to protect the health and lives of the public. A physician is not a guarantor of good results, and civil liability does not arise merely from bad results, nor if bad results are due to some cause other than his treatment. In case of doubt as to which of two or more courses is to be pursued, a physician is bound to use his best judgment. On questions of a medical or scientific nature as to what is the proper treatment to be followed in a particular case, only those who are qualified as experts are permitted to testify, the reasons being that lay witnesses, courts, and jurors are not permitted to say what is the proper treatment for a disease or how a specific surgical operation should be performed. This rule, said the court, is not to be considered as a judicial determination that the members of the medical profession have a monopoly on common sense, and is limited only to those matters clearly within the domain of medical science. If, in a given case, the bad results are so pronounced as to be apparent to anyone, and if what was done or not done in the treatment of a patient is so obvious and within the common everyday knowledge of persons generally, such facts may be testified to by persons other than physicians.

The Supreme Court said that the evidence consisted almost entirely of testimony of the pathologist who conducted the postmortem examination and of the attending nurses. All the questions and matters in issue were clearly within the realm of medical science, and, it may be said, there is not one iota of medical evidence to indicate that the defendant physician was guilty of negligence or malpractice in diagnosing or rendering medical care to the deceased. In fact, all the medical evidence affirmatively established that the defendant physician did conform to proper practices and usages in the light of all attendant circumstances. A point is made, said the Supreme Court, of the alleged statement by the defendant physician to the effect that perhaps the life of the plaintiff's wife might have been saved had a cesarean operation been performed. Assuming that such a remark was made, it constitutes no evidence that, under the circumstances and conditions existing prior to her death, and of which the doctor and nurses in the exercise of skill and diligence were well aware, it was negligence and malpractice not to perform a cesarean operation. Insofar as the defendant physician is concerned, concluded the court, matters concerning his professional acts in this case were matters solely within the realm of medical science and no evidence was introduced, expert or otherwise, to make out a prima facie case of negligence and malpractice on his part. Negligence is never presumed—it must be established, and until established by competent evidence, a jury has no function to perform. The plaintiff's evidence not only did not establish negligence it in fact refuted it.

So far as the liability of the defendant hospital is concerned, the Supreme Court said that the general rule is that a private hospital must exercise toward a patient such reasonable care as his known condition may require, the degree of care being in proportion to his known physical and mental ailments. Up until the actual time of delivery, said the court, there was absolutely nothing about the patient's condition to indicate there was anything unusual or abnormal about her case, or that it differed from any of the thousands of obstetric cases handled by the qualified and experienced nurses in attendance. In other words, so far as the patient's condition was known to the hospital and nurses, it was just another obstetric case, and there was no evidence to indicate or establish that she was not ministered to and cared for in the customary routine manner as her known condition required and demanded. Medical evidence was to the effect there was nothing abnormal about a transverse delivery and that very frequently external pressure is applied to the abdomen at the time of delivery.

As is the case with a physician, negligence against a hospital is never presumed, it must be established. Since the plaintiff's evidence did not establish negligence against either the physician or the hospital, the trial court was correct in granting the defendants' demurrer and that action was affirmed. *Goheen v. Graber, 309 P(2) 634 (Kansas, 1957).*

Revocation of License for Violation of Income Tax Laws.—This was a petition for a writ of mandamus to compel the review of an order of the Board of Medical Examiners, suspending the petitioner's license. From a judgment for the board the petitioner appealed to the district court of appeal, second district, division 1, California.

An accusation was filed with the board charging that the petitioner had been guilty of unprofessional conduct contrary to the Business and Professions Code, in that he was convicted of two felonies and criminal offenses involving moral turpitude. He had been convicted, following his plea of *nolo contendere,* of having wilfully and knowingly attempted to defeat and evade a large part of his federal income tax for 1947 and 1948. The board found that he had been convicted of the felonies in question and suspended his license for one year.

Section 2383 of the Business and Professions Code, as amended in 1951, provides: "The conviction of a felony, or of any offense involving moral turpitude, constitutes unprofessional conduct within the meaning of this chapter. The record of the conviction is conclusive evidence of such unprofessional conduct. A plea or verdict of guilty or a conviction following a plea of *nolo contendere* made to a charge of a felony or of any offense involving moral turpitude is deemed to be a conviction within the meaning of this section. . . ." The petitioner contended that a conviction of a felony, not involving moral turpitude, based on a plea of *nolo contendere,* is not a ground for disciplinary action against a physician. The court said that it is abundantly clear that the legislature intended that the conviction of a felony in and of itself, without any qualifications, constitutes unprofessional conduct. It is also clear that an "offense involving moral turpitude" does not necessarily have to be a felony. The record of conviction is conclusive evidence of the questioned conduct and by the very terms of the section a "plea of *nolo contendere* made to a charge of a felony or of any offense involving moral turpitude" is deemed to be a conviction within the meaning of the section. Other contentions of the petitioner were also overruled and the board's ruling suspending the petitioner's license for one year was accordingly affirmed. *Furnish v. Board of Medical Examiners, 308 P. (2d) 924 (Calif., 1957).*

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Syndrome of Relief of Angina Pectoris Following Myocardial Infarction. J. D. Matis and H. A. Solomon. Dis. Chest 31:622-633 (June) 1957 [Chicago].

Relief from severe and often intractable angina pectoris occurred after acute myocardial infarction in 7 men between the ages of 43 and 54 years. In the first 2 patients the angina pectoris became more intense after the first attack of myocardial infarction but was relieved after the second attack. In the 3rd patient the myocardial infarction afforded relief from angina pectoris which had been present for 4 years. There also was evidence of increased coronary reserve in that the patient was able to increase his activities greatly. Death, however, resulted from a new coronary thrombosis 2 years later despite the patient's apparent well-being. The 4th patient was able to return to his occupation as a salesman and did no longer have any chest pain with effort, 2 months after acute myocardial infarction. Because of increased endeavor his earning capacity 3 years after the infarction was greater than that of any previous year. The 5th patient obtained relief of chest pain after myocardial infarction. He remained completely active and without symptoms for 3 years, when death occurred suddenly while he was walking. The last 2 patients attended to their business without symptoms 3 and 6 months, respectively, after the myocardial infarction.

While these patients showed varying clinical manifestations and varying localization of the cardiac lesions, there was the common experience of relief from chest pain after acute coronary artery occlusion. Whether this relationship indicates a better life span remains to be studied. The likely explanation for the relief is that compensatory collateral circulation had developed during the period when angina pectoris was present. In addition to the concept of increased collateral circulation after narrowing of the coronary arteries, it has been theorized that transformation of an ischemic myocardial area into scar tissue might prevent the origin of painful stimuli. The latter concept seems less likely, because functional capacity after myocardial infarction was relatively good in the described patients.

Treatment of Cardiac Edema Resistant to Mercurial Diuretics. K. Mellemgaard. Ugesk. læger 119:641-647 (May 23) 1957 (In Danish) [Copenhagen].

In 6 of 12 patients with grave cardiac decompensation, electrolyte displacements afforded a probable explanation of the lack of response to mercurial diuretics. In the other 6 patients the electrolytes in the plasma were normal, but most often with serum chloride values in the lowest part of the normal range and total carbon dioxide values in the upper part. In all cases sensitivity to mercurial diuretics was restored by oral treatment with acetazolamide, with simultaneous development of a hyperchloremic acidosis or electrolyte displacement in this direction. After the decompensation disappeared, continued ambulant treatment was established in all the patients by alternating administration of thiomerin and acetazolamide or ammonium chloride. In all, continued compensation was attained in from 1 to 16 months. Three patients died without recurrence of the decompensation, 3 had recurrence in spite of the treatment, and 1 of these died from heart failure. In 1 case treatment had to be discontinued because of increasing uremia. Five patients continued well compensated during the treatment. When ammonium chloride was substituted for acetazolamide in 11 patients the effect was unchanged in 9, but there were considerable side-effects in 4 of these; in 2 patients treatment was stopped at once because of nausea and vomiting. No side-effects of acetazolamide were seen.

Two-Year Experience with Radioactive Iodine Treatment of Thyrotoxicosis. A. A. Atabek. Klinicheskaya med. 35:97-105 (April) 1957 (In Russian) [Moscow].

The authors treated 600 severe cases of thyrotoxicosis with radioactive iodine (I^{131}). Three hundred sixty patients were followed up for 6 months to 2 years after the termination of the treatment. There were 318 women (88.6%) and 41 men (11.4%). The patients selected for this treatment were those with severe types of thyrotoxicosis, those who were treated persistently with iodine preparations and with methyluracil without improvement. Twenty-six of these patients had recurrences after a thyroidectomy. After the follow-up of 6 months to 2 years, there was a complete disappearance of symptoms in 327 (90%). Sixteen patients (4.5%) developed a hypothyroid

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1948 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

state; 12 patients (3.3%) presented only mild symptoms of thyrotoxicosis. The cure was accomplished in 184 patients by a single dose of I^{131}, in 109 patients after 2 doses, in 25 after 3 doses, in 8 after 4 doses, and in 1 patient after 5 doses. In 12 patients there was failure to accomplish a complete disappearance of symptoms of the disease despite repeated administration of the I^{131}. The majority of the patients showed improvement in the symptoms in 3 weeks after the treatment was begun. Occasionally the improvement did not manifest itself before 4 or 5 weeks had passed.

Treatment with I^{131} is indicated in severe forms of thyrotoxicosis when operation is contraindicated because of a decompensated heart, liver involvement, thyrotoxic psychoses, postoperative recurrences, and advanced age of the patient. Treatment with I^{131} leads in 90% of the patients to diminution or to complete disappearance of the goiter and of the exophthalmos and to increase in weight, disappearance of tachycardia, and return to normal formula of the peripheral blood.

Test For Interatrial Communication. G. de J. Lee and T. M. D. Gimlette. Brit. M. J. 1:1279-1281 (June 1) 1957 [London].

The present paper describes a test which depends upon being able to alter the pressure within each atrium separately. It enables the clinician to arrive at a firm diagnosis for the otherwise symptomless patient with atrial septal defect. At rest, the net right atrial pressure was found to be 2-4 mm. Hg below the net pulmonary capillary pressure in normal individuals. Since the pulmonary capillary pressure and left atrial pressure in man are almost identical, a differential pressure relationship is thus established between the left and right atriums. These pressure differentials exist in small atrial defects but not in larger atrial defects where pressure tends to become uniform throughout as the atriums perform as a single chamber. With an oximeter earpiece used to record percentage oxygen arterial saturation and with brachial artery and intrathoracic pressures simultaneously recorded, the patient is asked to execute Valsalva's maneuver. This consists of blowing a mercury column to a height of 50 mm. for a period of 10 to 15 seconds. The patient repeats this maneuver after exercising against 2 car foot pumps. Patients who showed negative responses to the Valsalva tests were asked to perform the reverse precedure, i. e., the Muller maneuver. Finally, the patient's legs were raised during a continuous oximeter recording.

Should an atrial septal defect exist, then a right-to-left shunt of desaturated blood occurs across the defect due to the increased net right atrial pressure precipitated by the release of the previously engorged systemic veins. The Valsalva test was positive in all 12 patients where the diagnosis of atrial septal defect had already been proved. In one of these patients, the test was negative at rest but positive following exercise. Fourteen additional patients with evidence of left-to-right shunts gave positive Valsalva tests. The test was negative in only 2 cases of atrial septal defect. These 2 patients had large atrial septal defects and congestive cardiac failure at the time of the test. In very large atrial septal defects and in heart failure, there is no fall in brachial artery pressure but rather a square wave type response to increased intrathoracic pressure. The test has been negative only in the small number of patients studied with left-to-right shunts from causes other than interatrial communication.

A Curious Disease: Carcinoid of the Small Intestine with Hepatic Metastases and Cardiovascular Complications. R. Picard and J. P. Kerneis. Semaine hôp. Paris 33:2117-2123 (May 30) 1957 (In French) [Paris].

Intestinal carcinoids may appear in any part of the gastrointestinal system, even the stomach and the duodenum, but their favorite sites are the appendix, 65% of the cases, and the ileum, about 25%, the next most frequent site, the rectum, being affected in only about 10%. The character of the tumors varies greatly with their location: those found at the level of the appendix are usually benign and practically free from metastases, those in the rectum are accompanied by metastases in about 13% of the cases, but those in the ileal portion of the small intestine are potentially malignant if judged by the frequency with which they metastasize (30 to 50%). "Malignancy," however, is almost a relative term as applied to carcinoids, since in some patients incomplete operations in which metastases were left have been followed by 20-year survivals, while in other exceptional cases carcinoids may develop rapidly after the manner of carcinomatous tumors of the intestine. Neither the histological nor the cytological appearance of carcinoids provides any clue to their benignity or malignity.

Interest in the study of carcinoids was revived by the discovery of the hormone secreted by the Kultchisky cells. This hormone, Enteramine, which has the same chemical composition as serotonin, is probably responsible for an unusual syndrome of vasomotor disturbances and endocarditis that has recently been observed in patients with ileal carcinoids accompanied by extensive latent hepatic metastases. The first 4 cases of this syndrome were reported in 1952 by physicians in southern Sweden. Reports of additional cases have since been published in various other countries, bringing the world total to 30. The vasomotor syndrome is characterized by violent congestive crises in which the patient suddenly feels a tension and stinging heat in the skin and face. He is oppressed, anxious, and nauseated; weakness forces him to lie down, and he may even faint. Simultaneously, brick red, violet, or pallid spots appear, especially on the face but extending also to the trunk, the abdomen, and the limbs. This is the so-called "flush," and it is so characteristic that a diagnosis of carcinoid, later verified at operation, has in several cases been

ed on its appearance. These vasomotor attacks,
ch occur at the rate of from 4 to 25 a day, from
4 times a week, are accompanied by tachycardia
often by diarrhea and dyspnea. The cardiac syn-
me is no less extraordinary, consisting of endo-
litis of the right side of the heart with narrowing
he pulmonary artery and, often, tricuspid insuffi-
icy. These cardiac manifestations, which almost
ays occur in patients with long-standing latent
atic metastases, are apparently due to the enor-
isly increased amounts of serotonin found in these
ents. The antagonists of serotonin are, therefore,
ig intensively investigated in the attempts now
ig made to find a remedy for this extraordinary
dition.

ersplenism in Geriatrics. S. O. Schwartz and W. H.
tz. J. Am. Geriatrics 5:398-403 (April) 1957 [Balti-
e].

ypersplenism is a vague and poorly understood
i which implies abnormal splenic activity with a
ilting diminution of some or all of the cellular
nents of the blood. The mechanism is unknown,
none of the theories advanced to explain the con-
on has received universal acceptance. The con-
t of splenic inhibition of the release of cells from
marrow has been adopted by the authors because
ffords a simple approach to the problem. The
none theory, which is predicated on the regula-
by the spleen of the red blood cell, white blood
(granulocyte), and platelet levels, explains the
iction in cellular elements in the blood of patients
i enlarged spleens on the basis of overproduction
he splenic "hormone." This extensive regulation
xcessive splenic "hormone" would also account for
accumulation in the marrow of the normal pre-
sors of those elements lacking in the blood. The
cal conclusion, that splenectomy will correct the
iatologic conditions in hypersplenism, is borne out
ically. More detailed characteristics of the hyper-
nism syndrome include anemia, granlocytopenia,
thrombocytopenia either singly or combined. The
xistence of all 3 is termed pancytopenia. The de-
e of reduction of the cellular elements in the blood
iot a function of the size of the spleen, and the
erity of reduction is usually out of proportion to
which might be expected from the underlying
ase alone. Anemia is usually normochromic or
mocytic, mild to moderate degrees prevailing. The
ercellular marrow may further be involved by
nuloma, lipoid reticulosis, or lymphoma and leu-
iias. The spleen may vary in size from a just-
pable 250 Gm. to huge enlargement. Splenomegaly
be due to reticuloendothelial hyperplasia, con-
tion (splenic vein hypertension or splenic vein ob-
ction), local disease (sarcoid, lymphoma, and
dgkin's disease), infection (bacterial endocarditis,
ctious mononucleosis, rheumatoid arthritis, tuber-
osis, and malaria) or generalized disease (Gaucher's disease, lupus erythematosus disseminatus, leukemia, hemolytic anemia, Hodgkin's disease, and myeloid metaplasia). Hypersplenic manifestations may be relieved by treatment of the underlying disease, and the ultimate prognosis is dependent on such treatment as splenectomy. Although the immediate prognosis is good, it does not affect the underlying disease.

Hyperostosis Generalisata of Camurati-Engelmann Type. J. Roth. Harefuah 52:223-229 (May 1) (In Hebrew with English Summary) [Tel-Aviv, Israel].

An 18-year-old boy, an immigrant from Iraq, was found to have the rare generalized hyperostosis of the Camurati-Engelmann type. This disease involves the entire skeleton and muscles. The main symptoms are headache, pain in the extremities, and general weakness. The main pathological picture is hyperostosis and osteosclerosis. These cause symmetrical changes in the whole bony skeleton, especially of the skull and the extremities. The obvious thickening of the bones together with the endostosis brings about crowding out of the bone marrow. These changes effect only the diaphyses and not the epiphyses and the metaphyses of the bones. In the boy presented, the progress of the disease in the bony skeleton was followed with x-ray examinations over a period of 2 years. The physical examination revealed hepatosplenomegaly. There were no pathological blood changes. Examination of his family established that the disease is congenital and familial (3 generations of the family affected) and of a dominant inheritance. This disease as well as hyperostosis generalisata diffusa with pachydermia are congenital diseases, and both originate from disturbances in the development of the mesenchyma. Another theory is that sclerotic changes in the vessels of the bones and muscles are the cause of the disease.

Acute Porphyria. J. W. Fischer. Illinois M. J. 111:313-315 (June) 1957 [Chicago].

The author discusses the various types of porphyrins and of porphyria and shows that acute porphyria is in reality a chronic condition characterized by exacerbations and remissions over a period of time ranging from a few months to many years. The disease occurs in families, affects twice as many females as males, and is most common between the age of 20 to 40 years. The attack may manifest itself by abdominal or neurological symptoms. Between attacks the patient may be symptomless or suffer from ill-defined complaints such as vague abdominal pain, bizarre pain in the extremities, insomnia, depression, and weakness. The paroxysms of abdominal pains are in the nature of colic. This is frequently accompanied by nausea and vomiting and slight fever. Jaundice may occur. In women, attacks may be associated with menstruation. The pain is difficult to control and often worse at night. Spasms and rebound tenderness are not common. The leukocyte count may be normal or elevated. It is obvious that the condition may mimic appendicitis, biliary or renal colic, intestinal obstruction, or pancreatitis. It is, therefore, not surprising that these patients are often operated upon, and a "battle-scarred" abdomen attests to the obstinacy of this disease.

Mental symptoms may develop at any time in the course of illness. These are frequently simple emotional states, irritability and fatigue. Confusional, hallucinatory, or psychotic behavior may occur. The cardiovascular system is frequently involved, giving rise to hypertension, tachycardia, and electrocardiographic abnormalities. The diagnosis of porphyria should be borne in mind in any obscure nervous disturbance or ill-defined acute abdominal condition, particularly when they occur concurrently. Examination of recently passed urine is of major importance; this can be screened for porphobilinogen by the simple test devised by Watson and Schwartz. Patients with porphyria, like diabetics, should have on their person a written statement concerning their diagnosis so as not to lead the unwary surgeon to perform useless operations. Toxic agents, especially barbiturates and alcohol, should be avoided by these patients.

The Effects of Cortisone and Hydrocortisone on Water Diuresis and Renal Function in Man. L. G. Raisz, W. F. McNeely, L. Saxon and J. D. Rosenbaum. J. Clin. Invest. 36:767-779 (June, pt. 1) 1957 [New York].

The deficient diuretic response to water characteristic of patients with adrenal insufficiency can be rapidly corrected by the administration of cortisone. A number of observations, chiefly in experimental animals, suggested that administration of various adrenocortical preparations in large "pharmacological" doses also influences water diuresis in the normal organism. The present report describes the effects of large doses of cortisone and hydrocortisone on water diuresis, renal solute excretion, glomerular filtration rate, and effective renal plasma flow in adult male patients free from cardiovascular, renal, and endocrine disease. Three sets of studies concerning water diuresis were carried out.

The rate of urine flow observed during a maintained water load was regularly greatly increased during steroid administration irrespective of changes in the dietary intake and renal excretion of sodium salts. Serial studies in subjects on a salt-poor diet demonstrated an increase in maximal urine flow and in free-water clearance. The increased excretion of water was usually but not invariably accompanied by a small increase in sodium excretion, a gain in body weight, and sometimes by an increase in total solute excretion. The small rise in glomerular filtration rate noted during steroid administration did not parallel the increase in maximal urine flow. A single intravenous infusion of hydrocortisone regularly produced an increase in glomerular filtration rate, but without a consistent increase in the diuretic response to water loadi
The observations indicate that continued administr
tion of steroid in large doses influences the re
tubular reabsorption of water. It is suggested th
more free water is made available for excretion be-
cause of (1) a redistribution of solute reabsorption be-
tween proximal and distal systems or (2) an alterati
in the permeability of the renal tubular epitheliu
to water.

Contribution to the Knowledge of Acute Staphylococcic Enteritis Caused by Treatment with Antibiotics. M. Bassi and L. Gangitano. Sett. med. 44:501-505 (Oct. 15) 1956 (In Italian) [Florence, Italy].

The cases of 3 patients with micrococcic (staphylococcic) enteritis caused by treatment with antibiotic
are reported. The first patient, an 18-year-old femal
received treatment with antibiotics after being operated on for gangrenous and perforated appendici
The second patient, a 16-year-old male, receive
treatment with antibiotics after being operated on f
acute appendicitis. The third patient, a 17-year-o
male, received treatment with antibiotics because of
violent abdominal contusion incurred in a fall from
motorcycle. All patients had diarrhea. Pain in th
epigastrium or shock were not present before th
onset of diarrhea. The patients presented a choler
like syndrome with circulatory collapse, fast an
severe dehydration, and positive finding of Micrococcus pyogenes var. aureus. The symptoms occurre
after the administration of 1 million Oxford units o
penicillin, 8 Gm. of streptomycin, 2.4 Gm. of Terramycin, and 3 Gm. of chloromycetin given by parenter
route in the first patient; the administration of 1
Gm. of Terramycin, 500,000 units of penicillin, an
22 Gm. of sulfaguanidine in the second patient; an
after the administration of 2.4 Gm. of terramycin i
the third patient. The first two patients died and th
third survived. The first patient lived 4 days after th
appearance of the symptoms, the second patient
days. The condition of the third patient returned t
normal 5 days after the appearance of the symptom
The authors think that the syndrome was fatal in th
first two patients because these patients at the tim
they contracted enterocolities already had a seve
toxic infection and anaerobic germs. The general condition of the third patient was good at the time h
contracted enterocolitis.

SURGERY

Mild Rheumatic Carditis and Mitral Commissurotom
P. A. Kupriyanov, S. A. Gadzhiev and T. G. Bliestkin
Khirurgiya 33:26-32 (No. 5) (May) 1957 (In Russia
[Moscow].

The authors report on 126 patients who were subjected to a mitral commissurotomy. Rheumatic card
tis was suspected in 38 patients, while 88 patien
presented no clinical manifestations of carditis befo

operation. The histological study of an excised tion of the left auricle was carried out on all of operative patients. Signs of active rheumatic cess were demonstrated in 53 patients; 37 of these l Aschoff nodes, while in 16 there were present irect manifestations of the rheumatic carditis, such nonspecific infiltration of the interstitial tissue. icerbation of the rheumatic carditis in the postrative period was noted in 18 patients (14.3%); in 9 these the process was mild and had no effect upon general condition of the patient; in 9 patients a gressive course of rheumatic carditis was noted. e authors conclude that a mild rheumatic carditis ich does not yield to medical therapy does not istitute a contraindication to mitral commissuroty. Adequate enlargement of the atrioventricular fice improves circulation and leads to healing of the umatic carditis. Surgical treatment of mitral steno- in the presence of a mild carditis must be comied with active antirheumatic medical treatment. acerbation of the rheumatic carditis in the posterative period is more severe in the younger pants. As a rule, proper therapy, which consists of iibition of salicylates, corticotropin, antibiotics, and orbic acid, in the presence of adequate widening the ostium venosum, leads to healing. The active ocess subsides in the course of several weeks. Abice of clinical manifestations of rheumatic carditis fore the operation, as well as of histological data, es not guarantee against exacerbation of rheumatic rditis after the operation.

oplastic Disease of the Spinal Extradural Space: A view of 50 Cases. J. Mullan and J. P. Evans. M. A. Arch. Surg. 74:900-907 (June) 1957 [Chicago].

Fifty patients with spinal extradural tumor were ated by laminectomy and postoperative radiothery. Fourteen of the 50 patients had local tumors ising primarily in the spinal extradural space, in the ne, or spreading into the extradural space through e intervertebral foramens from the chest. Of the reaining 36 patients, 15 had reticular tumors and 21 id metastatic tumors. Six patients had a second eration, giving a total of 56 procedures. The results ere considered as good or excellent in 16 patients 2%), moderate in 13 (26%), and fair in 7 (14%); 14 itients (28%) were therapeutic failures. Causes of ilure were degree of malignancy, degree of damage the spinal cord before the operation, and errors of irgical judgment and of technique. Best results were btained in patients with the simpler radiosensitive imors; next most favorable were those in patients ith the reticular tumors, and least favorable were iose in patients with metastatic neoplasms.

Investigation, preferably by myelography, of each ase of suspected spinal extradural tumor is urged. atients in whom the histological appearance of the imor is unknown may be given radiotherapy under lose neurological observation where myelographic block is incomplete. If the pathology is known and the tumor is radiosensitive, radiotherapy should be given, provided that pressure on the cord is minimal. Urgent decompression and postoperative irradiation are indicated in all patients in whom compression is present and the tumor is insensitive to x-rays, or when the diagnosis is unknown, or even in those with radiosensitive tumors associated with marked neurological signs. The need for operation is urgent in the presence of spinal cord involvement, and time must not be wasted in prolonged investigation of a suspected primary lesion. It is difficult to say in the presence of complete paraplegia when it is too late to offer help, as good results were obtained in 1 patient after 2 months of paraplegia. None of the 6 patients who underwent a second operation obtained satisfactory results.

Use of Hypothermia in Intracranial Tumours. J. M. Inglis. Brit. M. J. 1:1335-1337 (June 1) 1957 [London].

Hypothermia has been found to be of undisputed value in cardiac surgery when temporary occlusion of one or more of the great vessels is required, in cerebral surgery when the main arteries supplying vital structures are occluded, and when a period of prolonged induced hypotension is desirable. Reduced body temperature subserves a protective function of vital organs by means of metabolic depression with reduced vulnerability to anoxia. Operative intervention in the brain stem is characterized by high postoperative mortality, and, although the reason for death is generally not clear, the hypothermia is of value in protecting the cells of the brain stem and diencephalon during operative procedures. Such a point is in need of statistical evidence which is not possible until larger numbers of cases are available. Two patients with craniopharyngioma, both of whom had displacement of the third ventricle, had the tumor completely removed surgically under hypothermia with the Birmingham hypothermia unit; they had an excellent postoperative course.

Conservative Surgery in Essential Facial Neuralgia. J. Guillaume and G. Mazars. Presse méd. 65:925-926 (May 18) 1957 (In French) [Paris].

Decompression of the trigeminal nerve by the extradural route was used by the authors with excellent results in 40 patients with essential facial neuralgia treated in 1954 and 1955. The operation can be performed with safety even in the oldest patients; it does not interfere with normal buccal and facial sensitivity; and it does not lead to ocular complications or masticatory difficulties. Relief from facial pain was obtained immediately in all but 4 of the patients, in whom slight rubbing of the trigger zone still elicited a few not very painful twinges for from 1 to 5 days after the operation. Transient recurrences of mild pain were noted by 3 patients 6, 12, and 14 months after operation, but only 1 patient had a genuine, lasting relapse. Paresthesias, which appeared in 5 patients, were variously described as "stiffness of the chin," "swelling of the lip," or "pinpricks on the cheek," but they were infrequent and much less disturbing than those observed after operations in which the nerve is severed.

The only objection that can be advanced against a decompression operation seems to be the possibility that the neuralgia may return at a later date. This objection cannot be definitively answered at present, because the number of patients who have had the conservative operation is not yet large enough, nor is the follow-up long enough, to provide the information needed for such an answer. It may be pointed out, however, that, if pain should recur after decompression of the nerve, neurotomy can still be performed. Neurotomy also retains its usefulness in certain atypical forms of neuralgia and in cases in which decompression cannot be satisfactorily accomplished, as for instance in patients in whom the Gasserian ganglion has been infiltrated with alcohol. The advantages of the decompression procedure for patients with essential facial neuralgia, however, are such that it should always be proposed first.

Surgical Management of Aortic Stenosis: An Evaluation of Techniques and Results. C. P. Bailey and W. Likoff. A. M. A. Arch. Int. Med. 99:859-886 (June) 1957 [Chicago].

There exist 3 distinctive individual methods for the surgical modification of aortic stenosis or closely allied disturbances at the outflow tract of the left ventricle. Transventricular and transaortic commissurotomy are closed-heart techniques, while the third and more recent procedure is the open-heart method, which involves the many principles and problems peculiar to open heart surgery as well as those related to mechanical valvular mobilization. Two hundred eighty-one patients with major aortic stenosis treated surgically by closed heart techniques were divided into 2 categories. Group 1 included those patients subjected to aortic commissurotomy for aortic stenosis alone, or in combination with other adynamic physiologically "insignificant" lesions, i. e., minor degrees of aortic regurgitation. Group 2 consisted of patients who required simultaneous aortic and mitral commissurotomies for coexisting stenosis of both valves either alone or in combination with other minor valve lesions. Group 1 patients had dyspnea (86.5%), fatigue (78.7%), pain of coronary artery insufficiency (48.2%), vertigo and syncope (30%), peripheral edema and other manifestations either alone or in combination (30%), and acute paroxysmal dyspnea (21.3%). The average duration of each major symptom in group 1 patients was less than one year, in contrast to the 4-year duration of major complaint in the group 2 patients. In the latter group, vertigo and syncope occurred less commonly and paroxysmal dyspnea more frequently, dyspnea and fatigue persisting as the most common complaint. Normal sinus rhythm was present in all but one of the patients with uncomplicated aortic stenosis, atrial fibrillation occurring in 47.7% of the patients with coexisting mitral stenosis. Increased x-ray size of the heart (2+) and a decreased second aortic sound were found in most patients in both groups. Clinical manifestations in patients with combined aortic and mitral stenosis resemble those of the latter disease much more than the former. Group 1 is further differentiated from group 2 in that left ventricular hypertrophy (60.6%) and complete left bundle-branch block are associated with the former group, while left bundle-branch block did not occur in the latter group. Surgery for aortic stenosis is not indicated when the aortic valve pressure gradient is less than 40 mm. Hg, save for some few patients with combined aortic and mitral stenosis.

The operative mortality rate for all patients in group 1 treated by a transventricular commissurotomy was 26.9% and by transaortic commissurotomy 16.4%. No deaths resulted where mitral and aortic stenosis coexisted as so-called "pure" lesions. In group 2 the mortality rate of all patients operated on via the transventricular method was 17.6% and of those operated on via the transaortic route 8.3%. Age was an important factor in the mortality rate in group 1, while increased heart size exerted a detrimental influence on both groups. The most dramatic postoperative improvement was observed in the symptom triad of angina, vertigo, and syncope, while the symptoms of fatigue, exertional dyspnea, and edema either disappeared or lessened considerably. Only 1 of the 11 patients subjected to open-heart commissurotomy died (ventricular fibrillation during surgery). Postoperatively, open-heart operations have had good results clinically, and in no patient has there been any suggestion of creation of valvular incompetency. The percentage of patients improved and the degree of subjective benefit obtained are not extended appreciably by the transaortic method in contradistinction to the transventricular technique. The open technique with use of a heart-lung bypass and retrograde perfusion of the coronary sinus, is advocated in all operative cases of congenital aortic stenosis and in most cases of extensive calcification of the aorta, as this technique routinely allows maximal relief of impedance without decreased valvular competence.

Electrical Ventricular Defibrillation: The Relationships Between Epicardial Burns and Late Mortality. A. B. Kortz and H. Swan. A. M. A. Arch. Surg. 74:911-917 (June) 1957 [Chicago].

Thirty dogs subjected to hypothermia, bilateral transsternal thoracotomy, and right ventriculotomy were divided into 4 experimental groups according to the agent or agents which they received to inhibit ventricular fibrillation, i. e., bethanechol chloride alone, Ambonestyl (2-diethyl-aminoethyl isonicotinamide) alone, Ambonestyl combined with bethanechol, a control group the members of which did not eive any pharmacological protection. Evaluation the mortality within the respective groups sug- sted a division of the whole series into 2 broad egories according to whether fibrillation had or not occurred at some time during the operative cedure. Of the 16 dogs that had fibrillation, de- rillation was achieved successfully in 15, but 11 of se died during the 7-day survival period. This resented a successful defibrillation of 94% but a e mortality of 74%. Of the 14 animals in which re was no fibrillation, all were living and well 7 s postoperatively. The high "late mortality" in gs in which "successful" defibrillation was accom- shed was considered to result from the method of fibrillation rather than from the arrhythmia itself. sidual epicardial burns over the lower left ventricle d cardiac apex were present frequently after elec- cal defibrillation. The late postoperative mortality s reduced from 74% to 10% in an additional experi- ental group of 10 dogs in which electrical defibrilla- n was successfully carried out with defibrillator ectrodes the bare faces of which were covered with line solution-soaked gauze sponge, cotton, or felt. Although ventricular fibrillation may be relatively nocuous when properly treated, the authors do not bscribe to the elective production of this arrhythmia ring open cardiotomy. They believe that a regular us rhythm with or without periods of elective car- ac asystole is desirable during intracardiac and tracardiac procedures. If ventricular fibrillation ould supervene, electrical defibrillation is readily ecuted. However, the production of myocardial and icardial burns during this experience may preclude equate cardiac function in the postdefibrillatory riod. Prevention of such burns is achieved by inter- sing saline solution-soaked gauze sponge, cotton, felt between the heart and the defibrillator elec- odes. This technique is not new, but its relation to stoperative mortality may not have been appre- ated previously.

he Diagnosis of Myxoma Cordis: Diagnosis Estab- hed Pre-operatively in Two Cases. F. S. P. Van uchem, J. Nieveen and L. B. Van Der Slikke. Car- iologia 30:353-366 (No. 6) 1957 (In English) [Basel, itzerland].

Myxomas have been observed at all ages and in oth sexes, but especially in persons between the th and 60th years of life, in 75% of whom these mors were located in the left atrium. Small tumors re relatively insignificant, and treatment may be eglected. Larger tumors cause circulatory disturb- nces. The fact that a tumor is mobile to some extent the basis of explanation for the effect of postural hanges on current signs and symptoms. Rapid pro- ression of signs and symptoms and a poor reaction cardiotonics are important diagnostic features. In he patients observed the left atrium was only slightly enlarged and the impression of the esophagus was slight. If the myxoma was of a firm consistency, powerful pulsations of the esophagus could occur synchronously with the ventricular contractions at the level of the left atrium. No esophageal pulsations were visible in a patient in whom the tumor was of a soft consistency while it was situated at a somewhat lower level. Cardiac catheterization shows an increase in pressure in the pulmonary artery and right ventricle. The absence of the characteristic X-dip in the pressure curves of the left atrium is absent in those patients in whom the capacity of the left atrium has been reduced due to the presence of a myxoma. The X-dip also disappears in atrial fibrillation, and a premature systolic peak is found in mitral insufficiency. No physical manifestations of either of the 2 disorders above were found, and no murmurs were audible in the patients. Angiocardiography reveals a gap in the shadow of the atrium.

Local Recurrence of Carcinoma After Anterior Resection of the Rectum and the Sigmoid: Relationship with the Length of Normal Mucosa Excised Distal to the Lesion. E. P. Lofgren, J. M. Waugh and M. B. Dockerty. A. M. A. Arch. Surg. 74:825-838 (June) 1957 [Chicago].

One hundred eight patients with local recurrence of carcinoma after surgical extirpation of a malignant lesion in the sigmoid colon or upper part of the rectum by the abdominal route (anterior resection) with end-to-end anastomosis of the intestine and with or without antecedent or concomitant performance of proximal colostomy to decompress the suture line were studied to determine whether a relationship exists between length of normal mucosa excised distal to the original lesion and the subsequent recurrence of malignant tissue in the proximity of the previously established anastomosis. No strikingly significant relationship was found in a comparison of 97 of the available original operative specimens with lesions of 102 patients who survived for 5 years after anterior resection and served as controls. Among other factors concerned in local recurrence of such lesions, lymphatic invasion in adjacent tissue is of importance, as evidenced by the fact that the incidence of lymphatic invasion among recurrent lesions was 16% higher than it was among nonrecurrent lesions. Yet the results of the study cast doubt on lymphatic invasion as a major factor in recurrence of malignant lesions in this location when it was demonstrated that the incidence of recurrences at the suture line was independent of the presence or absence of invasion of lymph nodes. The fact is noteworthy that the situation of recurrent lesions was closer to the anus than that of lesions among surviving patients.

Incomplete excision of the primary tumor explained 3 recurrences among 98 patients whose original operative specimens were studied macroscopically and microscopically. In 12 of these 98 patients the recurrences were attributed to incomplete excision of the satellite lymphatic or vascular permeation. Potentially neoplastic mucosa, with malignant regeneration, explained 7 recurrences. For the remaining 76 recurrences, all appearing at the line of suture, there was no acceptable explanation after gross and miscroscopic examination of 98 originally excised specimens and 27 recurrent specimens from this group. Although positive evidence that implantation of viable malignant cells into raw tissue surfaces is a major fact cannot be provided, this concept, which has been emphasized by other workers, seems attractive. If valid, it would explain the high proportion of recurrences at the line of suture independent of the presence of metastasis to lymph nodes, the relatively early recurrence of a lesion because of residual malignant tissue after the original operation, and the cause of the slight increase in the incidence of recurrences at the lower levels above the pectinate line. The concept might also explain the slight increase in recurrence of lesions when the length of excised normal mucosa distal to the lesion was small, a factor which in itself would enhance the danger of greater traumatic shedding, with increased density, of implantable viable malignant cells at the time of the original operation. Were this hypothesis acceptable, it could apply to 77% of the local recurrences in this study.

Prolonged and Complicated Forms of Primary Infection of Tuberculosis: Possibilities of Surgery. P. Giraud and H. Metras. Rev. españ. pediat. 13:141-155 (March-April) 1957 (In Spanish) [Zaragoza, Spain].

Primary infection with tuberculosis in a child develops in 2 stages: 1. An early stage, comprising general manifestations, which may become complicated with lymph node or meningitic dissemination. This stage lasts from a few weeks to several months and may be arrested by energetic antibiotic therapy of about 4 to 6 months' duration. 2. A secondary stage, marked by the involvement of the mediastinal lymph nodes, softening, and caseation, particularly in the bronchial tree. This stage, which may last for months and years, is very little affected by the modern therapy. The sequelae are bronchial stenosis; sclerosis and retraction of a lobar or segmental portion with possible bronchial dilatation; residual foci in bronchial or pulmonary lymph nodes which may remain latent for a long time but which are susceptible to reactivation. In some instances the anatomic study discovered a correlation between this lymph node involvement and the ulcerative tuberculosis of young adults. This is verified by bronchoscopy and by the examination of the primary infection of the patient's antecedents. In order to anticipate and to treat these sequelae and possibly to prevent adult tuberculosis, the authors suggest surgical therapy. They performed 50 operations, including ordinary lymph node removal and pulmonary lobar or segmental resection. The immediate prognosis was excellent. The follow-up prognosis, both anatomic and functional, was likewise good. The operat should be performed at a specialized place only wi use of a careful technique, antibiotics, and pr apparatus. A competent anesthetist is essential.

Pancreaticoduodenectomy for Chronic Relapsing Pa creatitis: Metabolic Defects Created by Total ar Subtotal Ablations. P. H. Jordan Jr. and M. I. Gro man. A. M. A. Arch. Surg. 74:871-880 (June) 19 [Chicago].

Six men between the ages of 34 and 63 years wi chronic relapsing pancreatitis, 3 of whom were trea by total resection of the pancreas and the other 3 b subtotal resection, served as subjects for conventio and radioactive absorption studies performed wit 2 months to 5 years after the operation. Pancreat (Viokase), given in doses of 6 Gm. a day, effective reduced the fecal fat and nitrogen losses that result from inadequate external secretion of the panc. The improvement in nitrogen balance which was a ciated with the administration of Viokase was n always commensurate with the degree of impro ment in nitrogen absorption. Radioactive iodine (I^{13} labeled triolein and radioiodinated serum albu (human) (RISA) were useful tools for the study of and protein absorption. Analysis of the radioacti of the stools was a more reliable index of absorpt than was the radioactivity of the blood. Absorption I^{131}-labeled oleic acid was significantly greater th the absorption of triolein. The importance of t observation as a therapeutic measure is unknow Iron-absorption studies with Fe^{59} were interpreted showing normal absorption of iron in the 3 patie with total pancreatectomy and increased absorpt of iron in 1 patient with subtotal pancreaticoduod ectomy.

Subtotal and total pancreaticoduodenectomy a effective forms of treatment for chronic relapsing p creatitis. The choice of total or subtotal pancreate tomy depends on the degree of exocrine and endocri deficiencies that exists as a result of inflammato destruction of the normal architecture of the pancre. If the functional capacity of the pancreas has alrea become severely compromised, resection is a justifia method of treatment, for perpetuation of the dise leads to a more crippling state for the patient th that which exists as a result of resection of the p creas, with postoperative metabolic effects not be significantly greater than the preoperative ones.

Postmortem Homografts in Extensive Burns. B. C Davis. Australian & New Zealand J. Surg. 26:244- (May) 1957 [Melbourne].

Large amounts of skin may be taken from a si donor after death and used immediately or set a in a refrigerator for later use. There is no disfig ment, time loss, or wound care necessary with suc donor. Permission must be obtained from the relati of deceased patients before cutting the homogr

Persons who have died with infective lesions, those with malignant disease, and those who have died more than 6 hours previously without the benefit of efrigeration are not suitable as donors of homografts. The postmortem homografts may be used immediately or may be kept wrapped in penicillin-saline gauze at he temperature of the ordinary household refrigerator. Just how long they will keep is not known, but the author has used with success autografts which have been refrigerated for 14 days.

The history of a 23-year-old man is presented in whom the use of postmortem homografts for the treatment of severe and extensive burns was considered to be life-saving. The fact that he was a healthy young man with a fighting spirit made a tremendous difference. Exposure treatment was ordered for the lower imbs and occlusive dressings for the upper limbs. It s difficult to expose circumferential burns, so Steinmann's pins were inserted into the heel to elevate the imb and thus reduce pressure on the posterior aspect. Estimations of the hemoglobin percentage and bacteriological examinations were made regularly throughout the course of the illness. Intravenous and antibiotic therapy was employed. When homografts are used, it is a good idea to scatter small autografts and pinch grafts between them. By this means, the autografts will be spreading by the time the homografts disintegrate. It is quite difficult sometimes to ell which are autografts and which homografts. The homografts appear viable until about the 3rd or 4th week, when they suddenly disintegrate.

NEUROLOGY & PSYCHIATRY

Methitural in Cerebral Electrotherapy. T. R. Robie. M. Soc. New Jersey 54:272-275 (June) 1957 [Trenton].

Melancholia or depression can generally be counteracted by electroshock therapy. The skeletal fractures which formerly were a major hazard in this form of therapy are now prevented by the use of succinyl choline chloride (Anectine). Succinyl's paralyzing effect endures for only 2 minutes. It is obvious that an anesthetic that endures for only 4 or 5 minutes would be ideal, and such is the case with methitural sodium, which the author used in the form of Neraval. There are minor differences in the method of administering methitural sodium (as compared to other barbiturate anesthetics) which must be followed. The latency period lasts from 30 to 50 seconds after intravenous injection before the anesthesia takes effect. Therefore, it is necessary to use the "two-syringe" technique, since the sense of suffocation from the succinyl would be more than the patient could stand unless the anesthetic had taken effect.

Another significant finding has come to light since methitural anesthesia was adopted routinely for all convulsive treatments. The authors had been observing severe hyperkinetic and loud verbalizing furors following electroconvulsive treatments in some difficult patients who required monthly maintenance treatments. These furors were so severe that restraint straps and chemical sedation were necessary. Since the authors used methitural anesthesia no furor reactions have occurred. They wonder if the fact that larger doses of succinyl can be safely given with methitural anesthesia might be the reason. The authors emphasize the importance of having the oxygen resuscitator available for patients who do not have spontaneous respiratory response from the temporary apnea following the treatment seizure. Often the glum and "melancholy" patient whose repetitive formula is "I just can't go to work" after less than half the necessary course of electroshock treatments has been completed alters his formula to a hearty "I'm anxious to get back to work now!" The need for psychotherapy remains imperative after the course of cerebroelectrotherapy. In all "melancholy" persons there are major mental conflicts requiring resolution.

Statistical Observations on the Distribution of Poliomyelitis Paralysis. M. Valle and M. Fasoli. Arch. ortop. 70:61-67 (No. 1) (In Italian) [Milano, Italy].

The authors report on a statistical study of the distribution of paralysis caused by poliomyelitis in 962 patients from all parts of Italy. A large number of the patients came from rural areas of northern Italy. The tibialis anterior, the gluteus medius, and the gluteus minimus were the muscles most frequently affected. The extensors of the lower limbs were affected frequently by paralysis, the flexors by paresis. The muscles of the arms were affected more frequently by paralysis than by paresis. The number of men was greater than that of women. Babies from 6 months to 1 year old represented the age group most frequently affected by the disease.

Papilledema in Poliomyelitis. H. A. Ladwig, J. H. Murphy, R. E. Murphy and E. O. Burgert. Nebraska M. J. 42:292-294 (June) 1957 [Lincoln].

The authors observed 3 patients with papilledema among 148 patients admitted to the poliomyelitis respiratory center. The histories of these patients are presented. The mechanism accounting for papilledema in poliomyelitis can only be speculated upon. The spinal fluid pressure is elevated in the acute phase in many patients who show no evidence of papilledema. Two things were noteworthy about the patients with papilledema. First, the papilledema was not present at the onset of the illness but rather appeared from 11 days to 5 months after the acute onset. Secondly, the spinal fluid protein level was elevated. This elevation of protein follows the destructive phase of the acute poliomyelitis. It is suggested that the presence of the high protein content in poliomyelitis may contribute to a diminished absorption of the cerebral spinal fluid by plugging the stomas of the arachnoid villi. The result of the slowed absorption is an increase in the cerebral spinal fluid pressure, thus causing the papilledema to occur after the acute phase of the illness. Another factor is presence of hypertension which may be associated with the acute phase of poliomyelitis. Several observers who have studied hypertensive retinopathy have concluded that papilledema is significant only of increased intracranial pressure and never due to local disturbances in the retina. It is suggested that further analysis of the protein content of the spinal fluid might determine whether this is a factor in the production of papilledema after poliomyelitis. One of the 3 patients presented illustrates the occurrence of progressive hypertensive retinopathy associated with poliomyelitis.

Lesions in the White Matter in Acute Poliomyelitis. I. Feigin. Neurology 7:399-403 (June) 1957 [Minneapolis].

The author describes lesions in the white matter of the cord which were revealed by autopsy in a 29-year-old woman, a 10½-year-old girl, and in 2 boys aged 16 and 17 years, respectively, who died of acute poliomyelitis. The most frequent pathological change in the white matter was the occurrence of perivascular lymphocytic infiltrates. In the first 2 patients, who died within 1 week after the onset of symptoms, focal areas of acute inflammation were noted in the white matter, characterized by an infiltration by a few polymorphonuclear cells and a more pronounced proliferation of microglial phagocytes. In 1 of the patients, these lesions involved the wall of a blood vessel and showed inflammatory changes and in 1 patient they showed necrotizing changes. Capillary thrombosis was observed in 1 lesion. Although occurring in patients with severe inflammatory changes in the gray matter and at the same cord levels as these severe changes, the lesions in the white matter were not generally situated adjacent to the gray matter but were more often present near the leptomeningeal surface. The leptomeninges overlying these zones showed inflammatory changes no greater than those noted elsewhere. Although the lesions were small, it is likely the fibers transversing them would be functionally impaired.

In the 2 boys with 10 and 17 days' of duration of the disease, larger lesions of a different character were observed in the white matter. These consisted of areas of marked rarefaction, within which a profound loss of axons and myelin sheaths had occurred. In 1 patient, markedly swollen and degenerated axons could be distinguished. An astrocytic response was negligible, while the microglial reaction was moderate in 1 patient and slight in the other. Inflammatory infiltration was minimal. The nature of these lesions is not entirely clear.

The lesions in the white matter are of much less significance than the severe lesions in the gray matter. It is not surprising that the functional disturbance relating to the lesions in the white matter has escaped clinical attention. Recent clinical reports have ind cated that sensory changes of a type which might b related to such lesions have been observed and th these should be included among characteristic clinica features of the disease.

Clinical Experiences with Meprobamate. H. Lehman and *T. Sirnes. Tidsskr.* norske lægefor. 77:419-4 (May 15) 1957 (In Norwegian) [Oslo].

From August, 1956, up to February, 1957, 67 me aged from 22 to 75 were treated with meprobamat in the psychiatric department for men, Ullevål Ho pital. Meprobamate probably causes fewer and le dangerous side-effects than chlorpromazine and Se pasil. The usual dosage was 1 tablet (0.4 Gm.) meprobamate 3 or 4 times daily. The duration of th treatment was from 1 to 86 days, with an average 26 days. The symptomatic effect was good in 17 of cases of neurosis, in 10 of 18 cases of alcoholism, n comania, and combined alcohol and drug abuse, a in 4 of 10 cases of psychic unrest in the postpsycho stage. Important side-effects were observed in only case, in a nonallergic patient, in whom itching e thema occurred after the first tablet. Meprobamate seldom effective in manifest psychotic conditions a in deeper neuroses. Earlier results and personal e perience indicate that meprobamate can be given a sedative simultaneously with electroshock. Chl promazine and Serpasil are regarded as contrain cated during electroshock treatment. Meprobamate especially suited for application in milder neuro reactions, where anxiety, depression, and muscul tension predominate; in the abstinence stage in alc holism and narcomania; for rest symptoms after ps choses; and for insomnia.

Clinical Aspects and Therapy of Poliomyelitis. Henckel and M. Hertl. München. med. Wchnsc 99:808-811 (May 31); 847-850 (June 7) 1957 (In Ge man) [Munich, Germany].

The authors report clinical observations on 83 ch dren who were hospitalized for poliomyelitis duri an epidemic in 1954. Twenty-three of the childr presented the symptoms of serous meningitis, and most of these 23 children the diagnosis of poliomy litis was only probable, because the authors were n able to ascertain the complement fixing antibodi They were able to rule out choriomeningitis, infecti with Coxsackie viruses, and leptospiroses. The clinic aspects were typical of poliomyelitis. In a few of th 60 children with paralytic forms only reflex chang could be ascertained, but most of them had severe forms that required long and intensive orthopedic treatment. Twenty-six children had spinal forms of paralysis. Ten children with the paralytic forms had spinal involvement at a high level. They had paralysis of the upper arm, of the neck muscles, and in the region of the 11th cranial nerve. In 2 of the children spinal forms of paralysis were associated with involveient of the bulbar-pontine region. Isolated paralysis f a single cranial nerve occurred in 14 children, inolvement of the facial nerve being particularly freuent.

The authors give particular attention to 3 therapeuc measures: the injection of gamma globulins during ie preparalytic stage, the administration of vitamin B$_{12}$, and the use of dehydrating measures (osmotherapy). The effect of gamma globulin on the prevenon of paralysis was demonstrated on large numbers f patients in the United States. They themselves gave amma globulin to 28 children with meningeal sympoms; 22 of these remained free from paralysis, wheres in 6 more or less severe forms of spinal paralysis eveloped one or two days later, the regression of which was about the same as in children who had ot been protected with gamma globulin. The authors ave vitamin B$_{12}$ by injection and orally to 38 of their atients with paralytic signs but were unable to eproduce the favorable results reported by others. Particular stress is put on osmotherapy by intensive ehydration with hypertonic solutions of glucose, Venotasin (extract of horse chestnut), mersalyl sodium Salyrgan), acetazolamide (Diamox), and the withrawal of fluid. Intensive dehydration proved espeially effective in the severest forms of poliomyelitis. This form of treatment proved effective again in 1956 n 4 children with severe bulbar-pontine forms of oliomyelitis with paralysis of deglutition. All of these hildren recovered.

GYNECOLOGY & OBSTETRICS

Diamox in Edema of Pregnancy. E. Balthrop and . M. Young. J. Florida M. A. 43:1201-1203 (June) 1957 [Jacksonville].

Of 323 obstetric patients, 38 with sodium retention nd edema of pregnancy were given 500 mg. of acetazolamide (Diamox) daily and were placed on a diet restricted in sodium. The remaining 285 patients with normal pregnancy did not receive acetazolamide. Seventeen of the 38 patients were therapeutic failures. Eighteen patients were benefited in that the potenially toxic or preeclampsic state was controlled. Thireen were greatly relieved of edema, and 5 were elieved completely. Three stopped loosing albumin n the urine, and 1 obtained remarkable relief from hypertension. Those patients who were weighed 48 hours after the beginning of administration of acetazolamide experienced maximal measurable loss in weight. This observation was instrumental in devising the 48-hour acetazolamide test to evaluate the sodium retention of the potentially toxic pregnant patient. The patient is instructed to restrict sodium intake; then she is weighed, given acetazolamide, and weighed again after 48 hours. A loss in weight of 2% of the total body weight indicates that further acetazolamide therapy is justified.

There is an increased reabsorption of sodium and water in the pregnant woman. This normal process is exaggerated in the preeclampsic or toxic state and is at least part of the cause of the eclampsia. Control of sodium and water excretion is therefore partly the answer to the control of eclampsia. Acetazolamide is a potent drug to increase sodium excretion in those patients who are potentially toxic.

Ten Years' Experience with Culdoscopy: An Analysis of 594 Cases. W. E. Josey, J. D. Thompson and R. W. Te Linde. South. M. J. 50:713-719 (June) 1957 [Birmingham, Ala.].

Culdoscopy was performed by 59 surgeons on 594 female patients between the ages of 9 and 69 years. The anesthesia used in most of the patients consisted of intravenous administration of thiopental sodium, usually supplemented by nitrous oxide and oxygen. Caudal and spinal anesthesia were used occasionally. Because of the difficulty observed in maintaining an adequate airway in the knee-chest position, patients who are to have culdoscopy with the aid of general anesthesia should be routinely intubated. The indications for culdoscopy were as follows: to rule out or to establish the diagnosis of ectopic pregnancy in 356 and of endometriosis in 51 patients; as part of endocrinologic investigation in 43; to search for a cause of unexplained abdominal or pelvic pain in 45; as part of investigation for sterility in 37; to determine the nature of pelvic masses in 31; for suspected pelvic tuberculosis in 21; and for miscellaneous conditions in 10.

Culdoscopy proved to be a valuable aid in the diagnosis of ectopic pregnancy in 323 of the 356 patients. It was also useful in 47 selected patients with suspected endometriosis, in 43 patients with unexplained abdominal pain, in 28 with pelvic masses of an uncertain nature, in the 21 with suspected pelvic tuberculosis, in 36 sterile patients, and in 42 with endocrine disorders. It appears that, if used successfully, culdoscopy will substantially reduce the number of patients requiring laparotomy for these conditions. Culdoscopy was regarded as unsatisfactory in 45 patients (7.6%), a relatively low failure rate which can be reduced by rejecting patients with a fixed mass or firm adhesions in the cul-de-sac and by attention to proper technique in inserting the trocar.

Culdoscopy is relatively safe, but it is not without danger when injudiciously employed. In 1 patient, misuse of the culdoscope resulted in the unrecognized perforation of the rectum and perhaps contributed to the death of the patient, which occurred 2 days later. This accident is extremely rare and is unlikely to occur if good judgment is exercised in the selection of patients. Extraperitoneal perforation of the rectum, in contradistinction to intra-abdominal perforation, does not constitute a serious injury. Of 28 patients with early intrauterine pregnancy found at the time of culdoscopy, 23 delivered uneventfully, and 4 of 5 who subsequently aborted had uterine bleeding and cramp-like pain on admission to the hospital, suggesting that abortion was threatening before the performance of culdoscopy. Culdoscopy probably does not interfere with the progress of a normal early intrauterine pregnancy.

Hypofibrinogenemia in Pregnancy. J. Tortora and J. C. Amico. New York J. Med. 57:2055-2058 (June 15) 1957 [New York].

The obstetric syndrome of incoagulable blood, if not promptly corrected, can result in fatal exsanguination. This defect is generally due to a decrease in circulating fibrinogen. There is little agreement as to how this condition is brought about. However, the concept that the uterus or its contents release thromboplastin into the blood, thereby setting in motion a normal clotting mechanism, that the resulting intravascular clotting causes increased utilization of fibrinogen, and that the liver is unable to replace this deficiency quickly enough to prevent hemorrhage, is fairly widespread. Other theories—that a lysin is produced which destroys the fibrinogen or that fibrinogen production is retarded—have not been satisfactorily demonstrated. Clinically, this syndrome occurs in abruptio placentae, amniotic fluid infusion, long retention of a dead fetus (usually due to Rh insensitization), fulminating eclampsia, abortion, and retained placenta. In nonobstetric patients it is found in drastic thoracic surgery, in association with operations for pancreatectomy, and in the experimental animal following extensive tissue damage. Normally, there is no significant alteration in the plasma fibrinogen levels during delivery or post partum. Treatment of this condition involves restoration of normal clotting by intravenous administration of adequate amounts of human fibrinogen along with replacement of blood loss. The literature does not contain any mention of hypofibrinogenemia associated with placenta previa.

Idiopathic Myocardial Failure in the Last Trimester of Pregnancy and the Puerperium. W. R. Meadows. Circulation 15:903-914 (June) 1957 [New York].

The authors report on 15 women, 13 Negroes and 2 white, between the ages of 22 and 44 years, with the syndrome of idiopathic myocardial failure occurring in the last trimester of pregnancy or during the puerperium. This syndrome is characterized by symptoms of congestive failure, which, early, is predominantly left sided; chest and abdominal pain; embolic phenomenon (occurring in 25 to 40% of the patients); acute hypertension; gallop rhythm; generalized dilatation of the heart; and T-wave inversion. In the 15 patients, the symptoms of night cough, hemoptysis, and paroxysmal nocturnal dyspnea were the earliest clinical manifestations of myocardial failure rather than its cause. Eleven patients made complete clinical recoveries and 4 died. Autopsies revealed lesions resembling those observed in similar cases unrelated to pregnancy. There was a soft, flabby, dilated myocardium; ventricular mural thrombi were observed as well as endocardial thickening of variable extent; and there were focal and diffuse areas of myocardial necrosis, especially in the subendocardial portion of the ventricular wall. The cause of the endomyocardial lesions is unknown. The syndrome tended to recur with subsequent pregnancies.

The authors' observations and those of other workers indicate that these patients are usually considered clinically to have either rheumatic or hypertensive heart disease, one of the rarer recognized forms of myocardial disease, or a disease suggested by symptoms coming from embolization of organs. Therapeutic efforts should not rest with the control of the symptoms of congestive failure but should include prolongation of bed rest until after the heart size has returned to within normal limits, when this objective is attainable. While bed rest alone is sufficient treatment in many patients, the need for digitalization becomes apparent early in others. Since embolization, when it occurs, is frequently a very early event in the course of the syndrome, effective use of anticoagulants would depend on their administration at the earliest possible moment. The frequency of recurrence of the syndrome with subsequent pregnancies and the predominance in the puerperium of this type of congestive failure over those with usual causes suggests that the relationship to pregnancy is not fortuitous.

***A Clinical Analysis of 8063 Cases of Painless Labor* by the Psychoprophylactic Method.** Ch'en Wen-Chen. Chinese M. J. 75:338-343 (May) 1957 (In English) [Peking, China].

According to the author, painless labor by the psychoprophylactic method was introduced by Russian investigators in 1949 on the basis of Pavlov's theory and has been carried out since then in the Soviet Union, China, France, and other countries. In this report he analyzes 8,063 deliveries carried out with the aid of the psychoprophylactic method at the Maternity Hospital of the Peking Medical College between January, 1953, and December, 1955. Candidates for the psychoprophylactic method of delivery (women pregnant from 32 to 34 weeks) were encouraged to speak about what they knew of the process of childbirth and to reveal their worries and fears. In 3 antenatal classes, held at weekly intervals, explanations were given on the anatomy of the female pelvic organs, the physiology of labor, and how pain might be eliminated. Breathing exercises considered fundamental in painless labor were explained, and after the last lecture breathing exercises were given under supervision.

On admission to delivery, the ward staff made the patients as comfortable as possible. The labor and delivery rooms should be quiet and pleasant. The accoucheur reviewed the lessons with each parturient, studied her mental and emotional reaction, and tried give her confidence in herself and her attendants. uring labor, she was informed from time to time of e progress of labor and the management given. She as instructed in how she could best cooperate dur- g the different stages of labor, in breathing, relaxing nd straining. To those who had not attended all the lasses, supplementary talks were given if time and onditions allowed. The effectiveness of the psycho- rophylactic method was graded excellent, good, fair, r failure. The 8,063 women in whom the method was sed accounted for 92.8% of the total of 8,671 de- vered at the hospital during the 3 years (1953 to 1955 clusive). The remaining women had failed to at- end the antenatal clinic or had attended for too hort a time to receive proper preparation. The method roved effective in 94% of the women in whom it was sed. The psychoprophylactic method was more effec- ve in multiparas than in primiparas. The results in total of 7,406 full-term, occipital anterior, spontane- us deliveries were compared with those of a control roup of 3,496 deliveries in regard to duration of bor and blood loss. The average duration of labor n the cases conducted by the psychoprophylactic ethod was shorter by 2.02 hours in primiparas and .56 hours in multiparas than in the control group. he average blood loss was also less in the former roup. The causes of failure and the use of medica- ion as an auxiliary to the psychoprophylactic method re discussed.

PEDIATRICS

enal-Vein Thrombosis in Newborn Infants of Dia- etic Mothers: Report of Two Cases. M. E. Avery, . H. Oppenheimer and H. H. Gordon. New England . Med. 265:1134-1138 (June 13) 1957 [Baltimore].

Thrombosis of the renal veins in infancy is an un- sual occurrence and is commonly due to dehydration r sepsis. Sometimes it occurs without any predis- osing cause and has been referred to as primary enal-vein thrombosis. A report on 2 newborn infants with renal-vein thrombosis in the absence of dehy- ration or sepsis is made, in addition to 2 other infants with the same condition reported on in literature. hey were all excessive-sized infants and had mothers with a history of diabetes. The anatomic diagnoses f one infant were history of maternal diabetes with uspected abruptio placentae and cesarean section, yperplasia of the islands of Langerhans, organizing hrombosis of the right renal vein and inferior vena ava, fresh thrombosis of the right intrarenal veins, emorrhagic infarction of the right kidney, jaundice, and extramedullary hematopoiesis of the liver and pleen. The anatomic diagnoses of the second infant were history of maternal diabetes, stillbirth, macera- tion, and extensive bilateral thrombosis, associated with calcification, of the renal veins. The evidence that the prediabetic state as well as manifest diabetes of the mother is associated with excessive-sized infants is unequivocal. A possible explanation for the association of renal-vein thrombosis and maternal diabetes is that the circulation is slowed, with stasis in the renal veins. The importance of awareness of this condition and early diagnosis is heightened by reports of survival after nephrectomy in at least 12 cases.

Acute Pancreatitis in Children. D. A. Blumenstock, J. Mithoefer and T. V. Santulli. Pediatrics 19:1002-1010 (June) 1957 [Springfield, Ill.].

Although acute pancreatitis is a rare disease in children, it occurs frequently enough to be considered in the differential diagnosis of abdominal pain and vomiting. Four new cases (in children ranging in age from 8 months to 6 years are presented and 36 previously reported cases are reviewed. The etiology was unknown in the 4 cases presented; 1 was associated with a perforation of the right hepatic duct. Each of the patients was operated upon at some time during the course of the disease, and the diagnosis of acute pancreatitis was confirmed. All patients ultimately recovered. The diagnosis of acute pancreatitis is rarely made in children before operation or autopsy because the disease is confused with the more frequent causes of abdominal pain and vomiting in this age group. However, the clinical history and abdominal signs may be suggestive of acute pancreatitis. The diagnosis can be confirmed by demonstrating elevation of the concentration of amylase in the serum, provided mumps is not present. In contrast to adult patients, acute pancreatitis in children is seldom related to disease of the biliary system. Acute pancreatitis in children may be produced by trauma, acute infection, and mechanical obstruction of the pancreatic ducts by round worms. The etiology of the majority of cases, however, remains unknown. The complications of acute pancreatitis in children include diabetes mellitus, retroperitoneal hemorrhage, pseudocyst formation, and hypocalcemic tetany. Treatment of uncomplicated acute pancreatitis should be conservative if the diagnosis can be made without operation.

Mast Cell Leukemia Presenting as Urticaria Pigmentosa: Report of a Case. W. J. Waters and P. S. Lacson. Pediatrics 19:1033-1042 (June) 1957 [Springfield, Ill.].

The concept of "urticaria pigmentosa" as a benign dermatological syndrome needs revision, since generalized organ involvement may be present. There have been some reports indicating that urticaria pigmentosa may be associated with a generalized disease, but these generally concerned patients in the older age group. The authors had the opportunity to study a boy with a generalized tissue mast cell involvement. They believe this to be the first recorded demonstration of tissue mast cells in the peripheral blood in a child. When 9 months old the child had been hospitalized for studies on the allergic origin of a chronic dermatitis, but studies and treatment were not rewarding. When he was admitted again when 5 years old, the mother reported that the rash had persisted and that secondary infection had often been a problem. She had noted for the past 2 years easy bruisability and difficulty of arresting hemorrhage from minor cuts. One week prior to admission a cough developed, with a temperature of 40 C (104 F), and the boy complained of generalized abdominal pain. The local physician noted hepatosplenomegaly and referred him to the hospital. On the basis of skin and lymph node biopsies as well as the study of the peripheral blood and bone marrow, a diagnosis of "urticaria pigmentosa" with hematological abnormalities was established, and the patient was discharged to be followed as an outpatient. Three months later he was readmitted with a temperature of 40.5 C (104.9 F), lethargy, and vomiting of yellow-green fluid and coffee-ground material. He was apathetic and had petechiae in the palpebral conjunctivae and on the soft palate; distention of the abdomen was noted, with the liver palpated down to the right iliac crest and the the spleen 4 fingerbreadths below the costal margin. The extremities were mottled, cold, and moist. The boy died on the third day.

At autopsy the cutaneous lesions appeared as dried, maculopapular eruptions on the abdomen, groins, and thighs. The lymph nodes were enlarged. On microscopic examination, an invasion of characteristic tissue mast cells was found in most of the organs. The tissue mast cells appeared as large polymorphic cells with acidophilic cytoplasm and relatively large rounded nucleus. The liver was the most massively involved organ. The subcapsular hemorrhage freely communicated with that in the substance of the liver without a demonstrable rupture on the surface of the organ. Death was believed to be due to exsanguination. With demonstration of the tissue mast cells in the peripheral blood and bone marrow the condition was classified as a form of leukemia. Tissue mast cells should be differentiated from blood basophils, as in the literature these are occasionally used interchangeably. Heparin and histamine determinations on frozen postmortem specimens of liver showed a concentration of approximately 100 times normal. Cortisone has been suggested as an inhibitor of the growth of the tissue mast cells. The boy died before such treatment could be instituted.

Skeletal Tuberculosis in Children Treated for Primary and Miliary Tuberculosis. L. Milgram. Am. Rev. Tuberc. 75:897-911 (June) 1957 [New York].

A group of 554 children, aged 12 years or less when first seen, with roentgenographic evidence of primary tuberculosis were followed up for 2 to 8 years. Of these, 206 received chemotherapy for at least one month and 348 were untreated. Thirty-five of the treated patients also had miliary tuberculosis. The survivors of the treated group were compared with the untreated group for the incidence of bone and joint tuberculosis after admission. During the period of follow-up, skeletal lesions occurred with greatest frequency among the survivors of miliary tuberculosis. The incidence was low among children treated for indications other than miliary disease, including those treated for bone and joint tuberculosis, and was lower than in the untreated group. Bone and joint tuberculosis occurred less frequently in patients treated with streptomycin and isoniazid than in those treated by the previously used thiazolsulfone (Promizole). It is suggested that the bones are infected early in primary tuberculosis and that chemotherapy acts on already established foci. There is evidence that at the beginning of treatment of miliary tuberculosis there is widespread involvement of the bone marrow. Suc foci probably account for the frequency of clinic bone and joint tuberculosis in patients treated f generalized tuberculosis.

Phenylketonuria in Child with Normal Intelligence Quotient: Comparative Biochemical and Psychodiagnostic Investigation on Two Girls of the Same Age. H. Bickel and W. Grüter. Ztschr. Kinderh. 79:509-521 (No. 5) 1957 (In German) [Berlin].

Psychometric tests on over 300 patients with phenylketonuria observed in homes for feeble-minded and in schools for backward children had demonstrated that the IQ was extremely low in a large percentage of children with phenylketonuria and below normal in all of them. The authors cite a 5-year-old girl with phenylketonuria who had a practically normal IQ o 91. Comparative biochemical and psychometric test were made on this child and on another child with a IQ of only 23. Despite the decided difference in in telligence, the plasma levels for phenylalanine, tyro sine, tryptophan, and alpha-amino-nitrogen, as we as the urinary excretion of phenylalanine and pheny pyroracemic acid, were practically the same in bot children. Certain differences in the excretion of phen and of indole bodies could not be explained. Tl authors point out that the lack of a direct relationsh between defective intelligence and the biochemic abnormalities that were found does not necessarily indicate that there is no causal connection between oligophrenia and the biochemical disturbances. Metabolites not yet identified, the action of antimetabolites, the sensitivity of which differs individually, and other factors may play a part in damaging the brain in early childhood.

The following factors speak against the possibility of an unconnected, merely concurrent hereditary transmission and for a true causal connection of the two defects: (1) the modification of the feeblemindedness by a diet with a low phenylalanine content; ( ) the peculiar characteristics of the mental deficiency; and (3) the presence of extrapyramidal disturbances. Dissociated intellectual defects indicative of organic brain changes were revealed by special psychometric tests in the child with the normal IQ. Patients with phenylketonuria in whom the intelligence is relatively ell preserved are good subjects for the differentiation the mental defects of this disease from that of ordiry "endogenic" feeblemindedness. The detection of normal IQ in a patient with phenylketonuria raises e question of the frequency of this concurrence nong the general population and among the appartly normal members of families with hereditary henylketonuria. It also indicates that caution is necsary in ascribing normal development to the early nset of a diet with low phenylalanine content.

neumonopathy Due to Staphylococcus in Early Inncy: Clinical and Statistical Study of 27 Patients bserved During the Period from 1954 to 1956. A. enevolo. Minerva pediat. 9:393-402 (April 7) 1957 n Italian) [Turin, Italy].

Pneumonopathy caused by staphylococci was obrved by the author in 27 infants, 17 male and 10 male, 8 days to 14 months old, during the years 1954, 55, and 1956. Sixteen infants had empyema, 3 biteral; and 11 infants, 4 with hypertension, had opneumothorax. Pulmonary localization was on the ght side in 20 patients, on the left side in 4, and lateral in 3. Ten infants were observed during the inter, 8 in the fall, 5 in the spring, and 4 in the sumer. Four infants had abscess, 2 otitis, and 1 perirditis. The leukocyte count was high in all the fants. The erythrosedimentation rate was high in the infants in whom it was measured. The Staphylococis, which was always isolated from the pleural pus, as pyogenes var. aureus in 25 patients and pyones var. albus in 2. Twenty-three patients were eated with antibiotics and 4 were subjected to surry. Best results were obtained in infants treated ith chloramphenicol. Very good results were obined in 3 infants treated with erythromycin. Large oses of antibiotics were used in all 23 infants. One fant was treated with antibiotics and sulfanilamide iven intravenously and 2 with antibiotics and staphycoccic anatoxin. Vitamins and other drugs were given cording to need. The children that were operated n were subjected to pleurotomy with application of permanent drainage. The operation did not have fect on 1 child who was subjected to a direct interention on the lung 3 days after the first operation. en infants died: 2 of the 4 observed in 1954, 5 of the observed in 1955, and 3 of the 15 observed in 1956.

OPHTHALMOLOGY

cular Metastases in Hutchison-Pepper Syndrome. K. Das Gupta and S. Roy. A. M. A. Arch. Ophth. 7:821-831 (June) 1957 [Chicago].

A 12-year-old boy was admitted to hospital with ain, proptosis and chemosis of the right eye, and a welling on the left side of the face on May 2, 1956. othing abnormal was detected in the left eye. Genral examination led to the diagnosis of Hutchison-epper syndrome. The patient gradually became worse. Five days after his admission signs of portal hypertension appeared There was extensor plantar response to the Babinsky test, showing also involvement of the spinal column. The liver mass, jaw swelling, and lump in the renal region, together with the proptosis of the right eye, were gradually increasing. The proptosis caused ulceration of the cornea, which sloughed out completely with extrusion of the lens. The eye was enucleated. A sudden change occurred on June 26, 1956. The swellings on the jaw, liver, and kidney regions regressed totally, except for a small nodule in the cheek. Proptosis was becoming reduced. There was nothing more unusual about the patient to be noticed. However, the nodule on the cheek, which had almost totally disappeared, began to increase again. Two other small nodules were noticed over the jaw on the left side on Sept. 22, 1956. Biopsy specimens showed the same malignant characteristics as were previously found. At the end of October the patient's condition deteriorated gradually. Edema extended to the whole of the face and the scalp. Subsequently, basal congestion developed on both sides, and the boy died on Jan. 12, 1957. Neuroblastoma of the adrenal gland with involvement of the liver and orbit and other metastatic deposits is uncommon but not a rarity. No mention of involvement of structures of the eye in neuroblastoma of the adrenal gland could be found in literature. In the patient presented, metastatic deposits were found in the iris, ciliary body, ciliary processes, choroid, sclera, and optic nerve of the proptosed eye. The cornea could not be examined.

The Eye Bank and Corneal Grafting Program. H. L. Ormsby and P. K. Basu. Canad. M. A. J. 76:919-921 (June 1) 1957 [Toronto].

Thirty-five keratoplasties have been performed by a research team including an ophthalmologist and a surgeon at the Toronto General Hospital. The operations have been surgically successful, and some improvement in vision has resulted in most patients. Graft opacification caused by a typical antigen-antibody reaction occurred in 1 patient with conical corneas 6 weeks postoperatively, and delayed graft opacification occurred in 2 other patients with interstitial keratitis. Eight eyes with conical corneas had successful full-thickness grafts, resulting in vision ranging from 20/20 to 20/40. In 10 patients with severe recurrent metaherpetic keratitis, 10-mm. lamellar grafts were applied, resulting in visual improvement in all patients and complete remission of symptoms, and there have been no recurrences of the herpetic infection. A longer follow-up will be necessary in the over-all group of 35 patients to establish the virtue of grafting in various diseases, but at this time it is felt that the scope of keratoplasty may be enlarged to include corneal scars caused by chemical burns, a major cause of corneal blindness in Canada.

THERAPEUTICS

Treatment of Pulmonary Tuberculosis by Viomycin Combined with Oxytetracycline. A. Pines. Tubercle 38:189-193 (June) 1957 [London].

Viomycin has been used in those patients with chronic pulmonary tuberculosis in whom tubercle bacilli resisted streptomycin, aminosalicylic acid (PAS), and isoniazid due to previous imbalanced treatment. Use of this antibiotic alone results in resistance within 3 or 4 months. The tetracycline group of drugs has some antituberculous action and has been used to avert resistance to streptomycin and isoniazid. The combination of oxytetracycline and viomycin has been reported to have had little or no effect other than to prevent deterioration (Tucker, 1954; Holland and others, 1956). In this series, viomycin and oxytetracycline were given daily. Those patients (15%) unable to tolerate oxytetracycline were given tetracycline instead. Following treatment, total cavitation was reduced from 104 to 58 cm., well-being was improved, bacillary content was reduced considerably, and the erythrocyte sedimentation rate did not approach pretreatment levels. Of the 20 patients so treated, 1 died 6 months after treatment was begun from uremia due to renal vein thrombosis secondary to amyloidosis. In 4 of the patients there was no radiological change, previous operation having failed in 2 of the 4 patients. In 5 of the patients there was little or no radiological improvement, subsequent operations being performed under this drug cover. In 5 there was moderate to considerable radiological improvement, and insurance operations considered necessary were successful in all. In the remaining 4 patients, in whom previous operation had been unsuccessful, treatment succeeded in arresting the disease, allowing the patients to return to a comparatively normal life, with drug treatment continued. No major complication occurred during the 10 operations performed during the treatment period. There was no change in sensitivity of the culture to viomycin and very little change in sensitivity to oxytetracycline in those patients whose cultures were still positive after treatment.

First Therapeutic Experiences with Prednisolone Hemisuccinate Given Intravenously to Patients with Bronchial Asthma. F. Sicuteri and M. Ficini. Sett. med. 44:604-606 (Dec. 15) 1956 (In Italian) [Florence, Italy].

Prednisolone hemisuccinate in a lyophilized form, dissolved just before use in 2 to 5 cc. of isotonic sodium chloride solution was given by one or more intravenous injections a day to 10 patients with bronchial asthma. A dose of 25 mg. of prednisolone was given at each injection. Bronchostenosis was the first symptom to be influenced. Remission of the symptoms was complete in 8 patients, and in the other 2 the symptoms were markedly improved. The drug had a very rapid effect. The objective and subjective symptoms of 1 patient improved 20 minutes after the jection. Total remission followed after 1 hour. T best effect was obtained within the first 12 to 24 ho after the beginning of the treatment. This effect, wh it was partial, did not improve even after an additio 24 to 48 hours of treatment. Four patients in wh the treatment had a very good effect in a very sh time had been treated previously with predniso given by mouth. The effect of the treatment w stabilized with administration of 29 to 39 mg. of drug given by mouth in 4 patients. The sympto reappeared in a mild form in all the remaining tients after the treatment was suspended. Total mission of the symptoms followed whenever the tre ment was repeated. The administration of place did not cause objective or subjective changes in syndrome. The treatment was well tolerated by patients. Irritation of the vein into which the d was injected was not observed. One patient had mild palpitation, another a mild psychic exciteme Marked changes of blood pressure or of the bo weight were not observed. The count of eosinop cells remained constantly low 2 or 3 hours after beginning of the treatment. Increased diuresis w observed in 5 patients.

Report on Experience with Treatment of Tubercul with Cyanoacetic Acid Hydrazide (Reazide). A. Hec Tuberkulosearzt 11:286-292 (May) 1957 (In Germ [Stuttgart, Germany].

Three hundred patients, 260 male and 40 fema between the ages of 15 and 60 years with pulmona tuberculosis were treated with cyanoacetic acid hyd zide (Reazide) for from 1 to 12 months. The da dose varied from 300 to 700 mg. (5 to 8 mg. per ki gram of body weight). Daily doses up to 600 mg. we tolerated well without undesirable side-effects. V tigo and headache necessitated reduction of the da dose to less then 700 mg. Treatment had to be disco tinued during the first month in 46 patients (15.3 Forty patients were treated for more than 5 mont up to 1 year. Of the 300 patients, 134 had producti exudative or infiltrating pulmonary tuberculosis, 1 had productive-cirrhotic pulmonary tuberculosis, a 62 were treated with the drug postoperatively aft pulmonary resection or were given combined collap therapy and cyanoacetic acid hydrazide therapy.

Increase in weight resulted from treatment wi cyanoacetic acid hydrazide in 226 patients (75.3 The erythrocyte sedimentation rate was either d creased or maintained at the normal pretreatme level in 192 patients (64%). An increase in lymphocy which can be interpreted as a favorable symp with regard to stabilization of the pulmonary proce was observed in 122 patients (40%). Seventy-six p tients (25.3%) reverted to negativity in the course cyanoacetic acid hydrazide therapy. Chest roentge grams revealed satisfactory results in 112 (47%) of t 238 patients with active pulmonary tuberculosis. T hest roentgenograms were unchanged in 70 patients 29.4%) and became worse in 40 (16.8%), and treatment had to be discontinued because of intolerance in 16 patients (6.7%) of this group. In the 62 patients with pulmonary resection, the condition of the remaining lung appeared to be stabilized despite the presence of residual tuberculous foci in 40 patients 64.5%); 12 patients (19.3%) had contralateral foci which remained unchanged postoperatively; 6 patients (9.6%) were therapeutic failures, and in 4 patients (6.4%) treatment had to be discontinued because of intolerance. Clinical and roentgenologic improvement thus were obtained by 50% of the patients. The mechanism of action of cyanoacetic acid hydrazide is related to that of isoniazid. The inhibitory effect exerted by the cyanoacetic acid hydrazide on the tubercle bacillus in vitro is somewhat less marked than that of the common chemotherapeutic agents. Streptomycin, isoniazid, and aminosalicylic acid are superior to cyanoacetic acid hydrazide, but the latter may be considered as an additional useful agent, particularly in patients with poor tolerance of isoniazid or in whom this drug is ineffective.

Clinical Experience and Experimental Studies with Tolbutamide. J. W. Craig and M. Miller. Diabetes 6:280-287 (May-June) 1957 [New York].

Tolbutamide is a sulfonylurea compound. Its effect on the blood sugar level was studied in patients with diabetes mellitus of varying types and etiologies. A blood sugar level–lowering effect of the drug was demonstrated in a partially pancreatectomized patient, but hyperglycemia and glycosuria were not reduced by tolbutamide in a totally pancreatectomized patient who received a constant dose of insulin during the period of study. The drug was effective in decreasing the blood glucose concentration in a patient with Cushing's syndrome, including diabetes mellitus, and in another patient with steroid diabetes secondary to prednisolone administration. The drug appears to diminish the endogenous formation of glucose without altering the rate of utilization of administered glucose. An inhibitory effect upon an antagonist or destroyer of insulin seems unlikely. The action of the drug is not altered significantly by adrenal cortical steroids.

The Mechanism of Action of the Sulfonylureas in Diabetes Mellitus. R. Levine and G. W. Sobel. Diabetes 6:263-269 (May-June) 1957 [New York].

The authors evaluated various hypotheses concerning the mechanism whereby certain sulfonylurea compounds lower the blood sugar level. The evidence collected since 1942 (when French observers noted profound hypoglycemic states in patients with typhoid who were being treated with a new sulfonamide preparation) favors the view that these drugs stimulate the beta cells of the islands of Langerhans to secrete stored insulin and perhaps also to produce more of the hormone. Furthermore, the sulfonylureas may under certain conditions influence the activity of the liver cells either by inhibiting the output of sugar or by reducing the activity of the insulinase system. The authors list the following observations as evidence of the pancreatic site of action: the ineffectiveness of sulfonylureas in pancreatectomized animals and human subjects; their ineffectiveness in eviscerated animals; cross-circulation data indicating the presence of an insulin-like substance; the hypoglycemic response in hepatectomized animals; the correlation of effectiveness in human subjects with the insulin content of the pancreas; the hypoglycemic response from small doses injected into the pancreatic artery; the histological changes in the beta cells suggesting a stimulating effect; the ineffectiveness in completely alloxanized animals with a definite hypoglycemic response in partially alloxanized animals; the ineffectiveness in juvenile diabetics and in some adults with unstable diabetes; and finally the demonstration of some of the phenomena known to follow the injection of insulin.

An additional hepatic effect of the sulfonylureas is suggested by the following observations: the difference in the rate of fructose-to-glucose transformation under the influence of the drugs; in vitro studies indicating decreased glucose-6-phosphatase activity following treatment with these drugs; failure to demonstrate in all instances metabolic phenomena known to follow the injection of insulin; and an insulin potentiating effect in depancreatized animals given large doses of the drugs. In view of the fact that the action of the sulfonylureas becomes evident generally in the presence of functioning beta cells or of exogenous insulin, it would seem that an influence on hepatic insulinase is more probable than a direct action on the enzymes of glucose production.

Clinical Experience with More than 100 Patients Treated with Orinase. S. J. N. Sugar. M. Ann. District of Columbia 26:293-296 (June) 1957 [Washington, D. C.]

One hundred thirty-one patients with diabetes mellitus were treated with tolbutamide (1-butyl-3-p-tolyl sulfonylurea, Orinase). Of these, 4 were aged less than 20 years, 12 were between 20 and 39 years, 61 were between 40 and 59 years, and 54 were between 60 and 80 years. The patients were hospitalized and insulin therapy was abruptly stopped; 2.5 Gm. of tolbutamide was given the first day, 1.5 Gm. the following day, and a maintenance dose of 1 Gm. daily thereafter. Blood sugar levels before and after breakfast were measured each day, and quantitative estimation of glucose in 24-hour urine specimens was performed. At the first sign of ketonuria, insulin was given. Control was considered good if the average morning blood sugar level was below 200 mg. per cubic centimeter and the 24-hour urine glucose level was less than 15 Gm. If control appeared inadequate, the dose was increased by 0.5-Gm. increments up to 4 Gm. per day. When patients seemed to be doing well they were given a supply of tolbutamide, were advised to test urines at home, and discharged, to be followed in the outpatient clinic.

Ninety-eight (75%) of the 131 patients were satisfactorily managed. More success was observed in those who had not received insulin previously but whose conditions were inadequately controlled with diet alone. Best results were noted in patients over 40 years of age whose known duration of diabetes was less than 10 years and who were taking less than 40 units of insulin. The exact method of action of tolbutamide is not completely known. Experimental evidence indicates probable stimulation of the beta cells of the pancreas. No serious side-effects were observed. Most prominent was a tendency to gain weight. Tolbutamide is not a substitute for insulin. When ketosis appears, insulin must be used.

Oral Preparation of Antidiabetic Agents: Report of a Fatal Case. J. B. Field and D. D. Federman. M. Ann. District of Columbia 26:297-300 (June) 1957 [Washington, D. C.]

The authors report a case of fatal hypersensitivity to carbutamide in a 48-year-old woman with diabetes mellitus of 3 years' duration. Fasting blood sugar levels ranged from 202 to 230 mg. per 100 cc. of blood. Liver function tests were normal except for 14% bromsulfalein retention in 45 minutes. During a control period, the 24-hour glycosuria averaged 13.6 Gm., the fasting blood sugar level was 211 mg., and the postprandial blood sugar level was 232 mg. per 100 cc. Carbutamide was given for 7 days in doses of 2.5 Gm. and then increased to 4 Gm. per day. Glycosuria decreased to 3 Gm. per day, the fasting blood sugar level to 139 mg. per 100 cc., and the postprandial blood sugar level to 165 mg. per 100 cc. The blood level of carbutamide was maintained at about 15 mg. per cubic centimeter of blood. The patient was discharged on a regimen of 4 Gm. of carbutamide per day. Urine tests for sugar at home remained negative. Eight days after discharge she noted fever, chills, anorexia, and back pain. Because of a urine sediment loaded with white blood cells, she was thought to have a urinary tract infection and was given an injection of penicillin and streptomycin. In the course of the next 3 days her symptoms disappeared. When she was seen again her blood sugar level was 126 mg. per 100 cc. and the carbutamide level was 13.6 mg. However, the white blood cells numbered 2,500, with 21% eosinophils. Unsuccessful attempts were made to have her stop the carbutamide therapy. The next day she suddenly collapsed and died.

Autopsy showed interstitial myocarditis with infiltration of eosinophilic polymorphonuclear leukocytes. The liver showed chronic inflammatory cells in the portal areas and some miliary granulomas with giant cells. There was no caseation. The portal lymph nodes showed similar lesions. The kidneys showed eosinophilic polymorphonuclear infiltrates. The final diagnosis was sudden death probably due to hypersensitivity to carbutamide. The features of fever, leukopenia, and eosinophilia are compatible with this diagnosis. So far no deaths have been reported from tolbutamide, but this drug has not been used for as long nor as widely as carbutamide. At present the exact place of these drugs in the armamentarium of the physician treating diabetes is not known. Because of their potential toxicity and limited usefulness to patients who might well get along with dietary control alone, it is apparent that the long-sought oral antidiabetic agent is yet to be found.

Deaths Associated with Steroid Hormone Therapy: An Analysis of 18 Cases. K. D. Allanby. Lancet 1:1104-1110 (June 1) 1957 [London].

Since cortisone and corticotropin are employed in diseases likely to be fatal, deaths may have been unjustly attributed to these steroid hormones. Details were collected on all deaths during treatment with cortisone or corticotropin at Guy's Hospital in an attempt to decide whether the treatment was responsible, how death occurred, and whether it might have been prevented. The histories of 18 patients who died during treatment are reviewed. No death during substitution therapy for Addison's disease or hypopituitarism or following adrenalectomy or hypophysectomy for carcinomatosis was included. The author believes that steroid therapy could be fairly blamed for 9 of the 18 deaths and was probably responsible for 2 more. In 2 patients therapy has not been held responsible, and it seems unlikely to have played a part in a further 2. In the remaining 3, death was quite possibly hastened or contributed to by cortisone or corticotropin. Infection caused most deaths in this series, at least 6 and possibly 7 of the 18. One of the most disquieting features of many of the recorded deaths during steroid therapy is the suppression or masking of the symptoms and signs of infection. Patients may appear well despite active infection and may collapse suddenly.

There is a serious risk of adrenal failure in patients who encounter added stress during steroid therapy. Surgeons are often reluctant to continue hormone therapy when operation becomes necessary, usually on the grounds of delayed wound-healing; but this risk has probably been overestimated, and, moreover, it seems unlikely to be much reduced by stopping cortisone administration only a day or two before the operation. Equally, physicians may feel bound to stop steroid treatment should infection occur. Sudden withdrawal of cortisone, however, leaves the patient without endogenous corticotropin, and, though adrenal failure is not inevitable, the logical course is to continue cortisone or corticotropin therapy, often in much bigger doses, until the risk is past. In 3 of the patients death followed intestinal perforation. Perfo-ation of the colon complicated ulcerative colitis in one patient and divericulitis in another; and in the third patient perforation involved the terminal ileum affected by periarteritis nodosa. Though perforation usually occurs through a preexisting lesion in the gastrointestinal tract, steroid hormones can produce peptic ulceration in previously normal persons; and, though the exclusion of patients with an ulcer history from steroid therapy will diminish the chances of perforation, the risk remains. Steroid therapy inevitably carries some risk, and regular and careful observation of all patients is imperative.

PATHOLOGY

Clinical and Anatomicopathological Aspects of Primary Arterial Pulmonary Hypertension: Report on 2 Recent Observations. B. Caini and P. Panuccio. Sett. med. 44:516-530 (Nov. 15) 1956 (In Italian) [Florence, Italy].

The authors report on 2 patients with primary pulmonary hypertension. The first patient, a 55-year-old woman, had a bronchopneumonia at the age of 25 and again at the age of 42. The patient had dyspnea on exertion, fainting spells, and acute and repeated precordial pain for 37 years previous to the examination. The second patient, a 37-year-old woman, presented dyspnea on exertion and continuous and sharp precordial pain for 7 years previous to examination. The patient was cyanotic for a short period prior to the examination. A marked diastolic murmur in the third intercostal space, accentuation of the second pulmonic sound, and diastolic thrill were heard on auscultation in both patients. Roentgenologic examination showed a marked prominence of the pulmonary arch in the left profile, an enlarged ventricular shadow, a normal left atrium, and a marked shadow of the large branches of the pulmonary artery near the hilus. A marked ectasia of the large arterial trunks was observed after introduction of a contrast medium; the small branches became slightly opaque. Catheterization of the heart showed hypertension in the whole vascular pulmonary tree. The 55-year-old patient died and was subjected to autopsy. Lesions of the arterial pulmonary circulation were noted.

Activity of Alkaline Serum Phosphatase in Patients with Tumor Metastases. M. L. Meischke-de Jongh, H. B. A. Hellendoorn and J. Gerbrandy. Nederl. tijdschr. geneesk. 101:859-862 (May 11) 1957 (In Dutch) [Haarlem, Netherlands].

Alkaline serum phosphatase activity is often increased in patients with skeletal or hepatic disorders. Tumor metastases in the bones and in the liver are also frequently accompanied by an increase in the alkaline phosphatase content of the serum. In order to obtain more information about the diagnostic value of the alkaline phosphatase content of the serum, the authors made studies on 437 patients with carcinoma and on 93 patients without malignant tumors. The alkaline serum phosphatase level in the 93 patients ranged from 1 to 7 Bodansky units. Of the 437 patients with carcinoma, 354 had no signs of hematogenic metastases, but about 50% of them had lymphogenic metastases. It was found that 34 of the 354 patients (9.6%) without hematogenic metastases had alkaline serum phosphatase activity in excess of 7 Bodansky units. Metastases to the lymph nodes did not seem to influence the level of alkaline phosphatase in the serum. Of the 83 carcinoma patients who had evidence of hematogenic metastases chiefly in the bones and in the liver 51 (61%) had an alkaline phosphatase activity exceeding 7 Bodansky units, and in 36 of these it was over 8 Bodansky units. The alkaline serum phosphatase level was higher on the average in those with osteoplastic than in those with osteolytic metastases, but the difference was not statistically significant. The authors conclude that the determination of the alkaline serum phosphatase activity is valuable in detecting metastases in the bones and in the liver.

Serum Enzymes in Muscular Dystrophy and Certain Other Muscular and Neuromuscular Diseases. C. M. Pearson. New England J. Med. 256:1069-1075 (June 6) 1957 [Boston].

The enzyme glutamic oxalacetic transaminase, hereafter referred to as transaminase, is widely distributed in animal tissues and is found in greatest concentration in skeletal and cardiac muscle. Normally, this enzyme is exclusively intracellular, as only a small amount is present in the circulation, although destruction of tissue will cause added amounts of enzyme to be liberated and appear in the serum. An increase in serum enzyme activity is indicative of cellular destruction and is the basis for a reliable laboratory determination of myocardial infarct or necrosis of the liver. In a series of 8 patients with progressive muscular dystrophy the serum transaminase level was elevated in 47%. Division of the patients into 2 groups by age showed that 90% of those 18 years or younger had elevated transaminase levels, whereas the reverse (normal to subnormal serum levels) was true of those over 18. No significant correlation exists with regard to transaminase level and the duration of the pathological process. Likewise, no direct correlation is apparent between transaminase levels and the severity of the disease, in that studies have shown that normal transaminase levels persist at both ends of the spectrum. A relationship between transaminase level and the estimated rate of dystrophic process is depicted, as is a finer correlation between elevated enzyme levels and the presence of pseudohypertrophy. Patients with secondary or neural muscular atrophy, including amytrophic lateral sclerosis, chronic polyneuritis, peroneal muscular atrophy, and extensive poliomyelitis, all showed normal transaminase levels.

There is an increase in the serum aldolase level in a very high percentage of children with multiple dystrophy. The persistence of high serum enzyme levels in children with muscular dystrophy suggests that a continuously high degree of striated muscle damage is constantly occurring over a longer period than previously suspected. The differentiation of primary and secondary (neural) muscular diseases has been achieved, as an increased level of transaminase, heart and liver disease excluded, is indicative of a primary myopathy. A normal level would eliminate the possibility of primary myopathy with any significant rate of progress but would not rule out the presence of dystrophy. An elevated transaminase level is an early guide to the efficacy of trial therapeutic measures as well as a valuable diagnostic tool.

Sex Chromatin in Choriocarcinoma (Chorioepithelioma) and in Carcinoma of the Skin. W. W. Oosterhuis and I. S. Levij. Nederl. tijdschr. geneesk. 101:901-903 (May 18) 1957 (In Dutch) [Haarlem, Netherlands].

The following question prompted this investigation: is the sex chromatin detectable in choriocarcinoma, and, if so, is there a relationship between the sex chromatin in the neoplasm and the sex of the fetus of the pregnancy preceding the development of the choriocarcinoma? The authors first searched for the sex chromatin in 100 skin carcinomas, 50 from men and 50 from women. In 97 of the patients the sex chromatin of the skin tumor was identical with that of the host. In 3 cases, so little sex chromatin could be found in the tumor cells that it was assumed the patients were male when in reality they were women. Studies were then made on 5 of 9 choriocarcinomas, the specimens of the other 4 being inadequately preserved for study. The histories of the 5 women indicated that in 2 of them the choriocarcinoma developed after the birth of male fetuses; in these women the sex chromatin of the tumors was male. Studies were made also on choriocarcinomas discovered in 7 men at autopsy. The cell nuclei of 3 of the tumors showed the female sex chromatin and the others the male sex chromatin. The authors point out that this corresponds to results of studies on teratoma of the testis, about 50% of which show a female nuclear structure.

A Case of Stevens-Johnson Syndrome Which Occurred After a Smallpox Immunization. Y. Boquien, D. Hervouet, G. Dauphin, R. Lhermitte and C. Robin. Presse méd. 65:956-958 (May 22) 1957 (In French) [Paris].

A patient presenting a Stevens-Johnson syndrome was referred to the authors 48 hours after a smallpox immunization. The tentative diagnosis of the referring physician was either smallpox or a general reaction to vaccinia. Treatment with erythromycin and cortisone, combined with a massive rehydration, proved effective. No secondary infection of the skin occurred. There were no ocular complications. Convalescence was rapid, and there was no recurrence. Stevens-Johnson syndrome nosologically is often classified wrong. Its first description as ectodermis erosiva pluriorificialis was made by Fiessinger and Rendu. They pointed out the connection of Stevens-Johnson syndrome with erythema multiforme, the peculiar confluent character of this eruption, the grave deterioration of the general condition, and the importance of dehydration. Its symptoms are sometimes confused with Reiter's disease or Behcet's disease. Stevens-Johnson syndrome is not well known. In this case there is a correlation between the smallpox immunization and the initial signs of the disease. The hypothesis of allergy is not convincing. Biotropism seems to be the most acceptable explanation. The authors have the impression that Aureomycin has brought the best results thus far, despite the fact that they employed erythromycin and cortisone. The combination of corticosuprarenal hormones with polyvalent antibiotics and the restoration of the hydric and electrolytic equilibrium will probably improve the prognosis in even the severe cases.

Susceptibility of Enterococci and of Hemolytic Streptococci of Groups A, B, C, and G to Five New Antibiotics in Vitro. W. F. Jones and M. Finland. Am. J. Clin. Path. 27:528-533 (May) 1957 [Baltimore].

As part of a general study of the changing patterns of resistance of common bacterial pathogens to various antibiotics and during the study of 5 new antibiotics, it became of interest to determine the in vitro susceptibility of various pathogenic streptococci to these new agents. The results of tests for the in vitro susceptibility of recently isolated strains of specifically grouped streptococci to the 5 new antibiotics and erythromycin are presented graphically. Weight for weight, erythromycin was the most active and cycloserine the least active; novobiocin was appreciably less active than the other 3 antibiotics studied, namely, oleandomycin, spiramycin, and streptogramin, each of which exhibited some cross resistance with erythromycin. Of the 3 erythromycin-like agents, spiramycin was the most active against enterococci and streptogramin against the strains of other groups; oleandomycin had an intermediate activity against all of the groups tested. Strains of groups A, B, C, and G ranked in that order in their susceptibility to streptogramin and cycloserine; otherwise, there did not seem to be any relation between (1) the specific groups of hemolytic streptococci or the species of enterococci (group D streptococci) and (2) the susceptibility to each of the antibiotics included in this study.

The Thymol Turbidity Test in Screening of Blood Donors. E. R. Jennings, W. M. Hindman, B. Zak and others. Am. J. Clin. Path. 27:489-502 (May) 1957 [Baltimore].

Blood transfusions involve the hazard of the development of serum hepatitis, despite efforts to screen blood donors by medical history and hepatic function tests. Owing to the widespread confusion in regard to the usefulness of a hepatic function test for the screening of blood donors, the present study was begun with the hope that the observations would provide a means of determining whether the risk of serum hepatitis is increased when blood is transfused from donors who have significantly elevated thymol turbidity values. For the purpose of this study, an elevated thymol turbidity level was defined as that in excess of 8 Shank-Hoagland units. Blood from donors whose values for thymol turbidity exceeded this level was referred to as having come from "high thymol" donors. The test that was used is a modification of that described by De la Huerga and Popper. Thymol turbidity tests were performed on blood from 14,755 donors. Serum from 567 of these persons had values for thymol turbidity that were greater than 8 Shank-Hoagland units (3.8%). Follow-up examinations of 193 recipients of whole blood from donors with a thymol turbidity level greater than 8 units revealed 10 patients with serum hepatitis and 5 with possible serum hepatitis. In a control group of 603 recipients of blood from donors whose values for thymol turbidity of serum were normal or not known, follow-up examinations revealed no instances of serum hepatitis and 2 instances of possible hepatitis. The authors believe that the hazard of serum hepatitis is greatly increased when blood is transfused from donors whose serums have significantly abnormal values for thymol turbidity.

Histamine Inactivation Power of Blood Serum in Rheumatic Fever. J. L. Parrot, P. Mozziconacci, C. Danelatos and C. Laborde. Semaine hôp. Paris 34:2157-2159 (June 6) 1957 (In French) [Paris].

An attack of rheumatic fever is accompanied by a considerable reduction in histamine inactivation power of blood serum. This seems to be related to the patient's reactional capacity rather than to the streptococcic infection. Low histamine inactivating power seems to persist in patients with cardiac involvement. The histamine inactivation power is normal in cases uncomplicated by cardiac involvement, as in patients with mitral lesion but without previous rheumatic fever. The absence of histamine inactivating power of blood serum was found in Bouillaud's disease, asthma, urticaria, Quincke's edema, eczema, migraine, and acute gastric and duodenal ulcer. The study of the variation of the histamine inactivation effect can, with certain limitations, be added to other biological tests that help indicate the diagnosis and possibly the prognosis of Bouillaud's disease. The authors observed the histamine inactivating power of blood serum of 60 patients (52 children, 8 adults) with rheumatic fever. Twenty-five patients with the first rheumatic attack had a very low rate of histamine inactivating power, up to 5%; 10 patients with progressive rheumatic fever had a low rate, between 5 and 10%; 18 patients with static rheumatic fever had a rate below normal, between 5 and 20%; 7 patients with static rheumatic fever and no cardiac lesions had a normal or slightly lower than normal rate, between 20 and 30%. The authors are unable to say whether the variation of the histamine inactivating power proves that an attack of rheumatic fever is an allergic reaction predisposing to rheumatic fever; that is, whether the variation in the histamine inactivating power is the effect or the cause of the disease. In the absence of allergic antecedents, such as asthma, eczema, or urticaria, the study of the rate of histamine inactivating power variation can help in the diagnosis of the articular or cardiac rheumatic attack. This study adds arguments to the theory that rheumatic fever is an allergic reaction to the streptococcic infection.

RADIOLOGY

Congenital Malformation of the Renal Artery, a Cause of Hypertension. F. Isaac, T. H. Brem, E. Temkin and H. J. Movius. Radiology 68:679-687 (May) 1957 [Syracuse, N. Y.].

Although the validity of Goldblatt's experiment showing that interference with the renal arterial blood flow through one or both kidneys can result in sustained hypertension has been opposed by some investigators, there is general agreement that there are at least certain forms of renal disease which definitely represent the human counterpart of the experimental renal hypertension of Goldblatt. The authors observed 3 patients in whom hypertensive disease was associated with congenital malformation of one or both renal arteries. In the 2 in whom the malformation was unilateral, significant improvement is believed to have been achieved by nephrectomy. The incidence of such cases is probably higher than might be inferred from the literature. The malformation may take the form of a cirsoid angioma, giving rise to a characteristic deformity of the ureter by which its presence can be suspected on the excretory urogram. This, in turn, furnishes an indication for abdominal aortography, by which the diagnosis can be definitely established. If the disease is unilateral, the condition may be amenable to surgical cure by nephrectomy. It is assumed that the degree of improvement following nephrectomy is inversely proportional to the length of time that hypertension had existed. It is emphasized, therefore, that consideration be given to this possibility at the first discovery of "essential" hypertension, particularly in the young adult.

Gastrointestinal Roentgen Findings Due to Untoward Effects of Hexamethonium. I. K. Ettman, C. D. Bouchillon and H. H. Halford. Radiology 68:673-678 (May) 1957 [Syracuse, N. Y.].

Hexamethonium as a ganglionic blocking agent inhibits the transmission of nerve impulses through both sympathetic and parasympathetic ganglions of the autonomic nervous system. It causes generalized vascular relaxation, dilatation, and hypotension. In the gastrointestinal tract it produces gastric hypotonicity and hyposecretion of both the acid and mucous elements and has therefore been used in the treatment of peptic ulcer. The authors observed in the radiology department several interesting problems and potential hazards involved in the use of hexamethonium. They present the histories of 3 patients to show the value of roentgenography in the early detection of untoward effects of hexamethonium on the gastrointestinal tract. Gastric retention and adynamic ileus are the more serious complications resulting from treatment with hexamethonium. Suppression of secretion and motility in the stomach may cause retention of food particles, simulating gastric neoplasm. It is possible that toxic amounts of the drug may accumulate in the stomach and either be released into the duodenum in an unpredictable fashion or vomited, thus doing the patient no good and making evaluation of the dosage schedule difficult. Adynamic ileus is almost certain to ensue if supportive measures are not instituted early and adjusted according to the needs of the individual. The more severe cases may simulate organic obstruction. A simple scout film of the abdomen demonstrates the changes produced by the drug, frequently before clinical manifestations develop. With constant attention to and control of untoward reactions in the gastrointestinal tract and other body systems, the continued application of this useful adjunctive drug in the treatment of hypertension is justified.

ANESTHESIA

Re-evaluation of Paravertebral Lumbar Sympathetic Block in Treatment of Peripheral Vascular Disease. D. L. Crandell and W. G. Page. Anesthesiology 18:454-460 (May-June) 1957 [Philadelphia].

Skin temperature studies were utilized to compare the effectiveness of sympathetic block and sympathectomy with 2 relatively new adrenolytic and sympatholytic agents in producing vasodilatation in 208 patients with peripheral vascular disease of the lower extremity, 20 of whom had Raynaud's disease, 6 phlegmasia cerulea dolens, 61 acute thrombophlebitis, 18 thromboangiitis obliterans, 89 arteriosclerosis obliterans, 4 sudden arterial occlusion, and 10 postphlebitic syndrome. The adrenolytic agent, azapetine (Ilidar) phosphate (1 mg. per kilogram in 250 cc. of sodium chloride solution) and the sympatholytic agent trimethaphan camphorsulfonate (Arfonad) (2 mg. per kilogram in 250 cc. of sodium chloride solution) were administered intravenously until the maximal response was obtained or adverse side-reactions occurred. Paravertebral lumbar sympathetic block was performed with the single-needle technique, with insertion at the level of the second lumbar vertebra and injection of 30 cc. of 0.15% tetracaine hydrochloride. Evidence of complete sympathetic blockade and sympathectomy was determined by the disappearance of the sympathogalvanic reflex.

The intense vasospasm observed in Raynaud's disease showed a much greater response from sympathetic block than from the vasodilating drugs. In patients with thromboangiitis obliterans, with its varying degrees of vasospasm and organic obstruction, the results were better with sympathetic block. The results of sympathetic block and of the vasodilating drugs were similar in the patients with arteriosclerosis obliterans. Sympathetic inhibition of the lower extremity which is produced by sympathetic block more accurately determines the degree of vasoconstrictor tone and is a valuable aid in the differentiation between vasospasm and organic obstruction. In arteriosclerosis obliterans with normal vasoconstrictor tone positive results with sympathetic block where comparable with postlumbar sympathectomy studies. Negative results with sympathetic block were attributed to little or no vascular tone or to the slow progressive development of collateral circulation which may follow surgical sympathetic inhibition. Evidence of vasodilation in extremities effected by severe chronic arterial occlusive disease was much less impressive. Digits revealing a decrease in temperature and increased pain after sympathetic block may become gangrenous after sympathectomy. Sympathectomy is contraindicated when this phenomenon occurs. Sympathetic block was most effective in diagnosis (presence or absence of spasm), prognosis (to determine the potential effect of a surgical sympathectomy), and in treatment (traumatic or infectious spasm). Thus, even with the advent of newer sympatholytic and adrenolytic drugs an adequately performed sympathetic block continues to be a valuable tool in the anesthesiologist's armamentarium in the management of peripheral vascular disease of the lower extremity.

Evaluation of Electrocardiography During Congenital Heart Surgery. R. M. Smith and H. P. Wiley. Anesthesiology 18:398-412 (May-June) 1947 [Philadelphia].

Electrocardiographic tracings were taken during 103 operative procedures, 17 of which were performed for patent ductus arteriosus, 15 for coarctation of the aorta, 21 for atrial septal defects, 37 for tetralogy of Fallot, and 13 for pulmonary stenosis. Hypothermia or bypass techniques were not used in these operations. The anesthetic agents used included cyclopropane, cyclopropane-ether, nitrous oxide-ether, and nitrous oxide, thiopental, and curare. Preoperative medication consisted of pentobarbital sodium, morphine or meperidine, and atropine or scopolamine. No patient was digitalized in preparation for operation, but many of those with atrial septal defects were given quinidine to reduce myocardial disturbance. Calcium chloride was used as a cardiac stimulant during the course of several operations. Electrocardiograms were obtained in all patients just before the operation; during the start of the operation, opening of the pleural cavity, mediastinal dissection, clamping and releasing major vessels, entering the pericardium and heart, valvulotomy, periods of rapid blood loss or cardiac depression, closure of the pleural cavity, completion of surgery, and extubation; and after completion of the operation.

Of the 103 patients studied, only 11 showed normal reoperative electrocardiograms. The abnormalities iown by the electrocardiograms in the remaining 92 atients consisted of axis deviation, ventricular hyperophy, and bundle-branch block. During the surgical itervention the electrocardiographic tracings were gular throughout in 39 patients, sinus tachycardia as observed in 58, ST deviation in 10, auriculoventriclar nodular rhythm in 21, auriculoventricular block n 5, ventricular premature contraction in 37, ventricur paroxysmal tachycardia in 6, sinus arrest in 3, and entricular fibrillation in 2. Thus a variety of arrhythnias were observed, and their occurrence varied coniderably with the primary cardiac defect as well as vith the type and phase of the operation. From a ractical standpoint, most of the arrhythmias seemed f little importance with the exception of such terminal racings as sinus arrest and ventricular fibrillation. In atients with these arrhythmias, clinical observation sually preceded electrocardiographic changes. Elecrocardiography was of definite value in a few paients, especially in differentiating sinus bradycardia rom auriculoventricular block and auricular tachyardia from the more serious ventricular tachycardia. n many patients the conduction defects and arrhythnias found were clinically unimportant, nonspecific, r so late in appearance that the underlying problem vas already obvious. Consequently, the value of the lectrocardiogram seems limited. In the presence of reexisting myocardial weakness, however, and during perations involving direct stimulation of the heart uch a valvulotomy and atrial septal closure, sufficient nformation was gained by electrocardiography to nake its use definitely advisable.

A Study of the Cardiovascular Changes During Cooling and Rewarming in Human Subjects Undergoing Total Circulatory Occlusion. E. Blair, R. R. Austin, S. G. Blount Jr. and H. Swan. J. Thoracic Surg. 33:707-718 (June) 1957 [St. Louis].

The authors report cardiovascular observations made in the operating room throughout the course of intracardiac surgery in 23 patients between the ages of 3 and 35 years, subjected to general hypothermia with sigmoid temperatures between 26 C (78.8 F) and 31 C (87.8 F). Thirteen patients were operated on for interatrial septal defects, 3 for Tetralogy of Fallot, 6 for pulmonary valvular stenosis, and 1 for infundibular pulmonary stenosis. After premedication with meperidine (Demerol) hydrochloride and scopolamine, the patient was anesthetized with ether and a no. 18 Cournand needle was placed into the brachial artery. A polyethylene catheter was introduced by way of an anticubital vein into the subclavian vein or superior vena cava. Pressures were transmitted to a recorder. The patient was then placed into a tub of tap water and immersed to the neck. Ice was added to the water, and the temperature of the bath soon dropped to 5 C (41 F) or lower. When the desired level of temperature was reached, the patient was lifted out of the tub and onto the operating table. When the actual procedure within the heart had been accomplished, rewarming by short-wave diathermy was instituted. Attempts were made to determine heart rate, blood pressure, and venous pressure during the induction and initial stage of hypothermia, total circulatory occlusion, release of occlusion, and rewarming.

On cooling there was a transient elevation in blood pressure, followed by a fall which did not reach its maximum until 30 minutes after the sigmoid temperature had reached its lowest point. The pulse rate fell progressively with cooling, and the temperature and the pulse rate reached their lowest levels simultaneously. Blood pressures and pulses were lost to auscultation and palpation at varying points during cooling; at the times of the "clinical disappearance" both blood pressure and pulse rate were quite adequate, as demonstrated by direct measurements. The mechanism of the "clinical disappearance" is believed to lie in the physical state of the large arteries, which become rigid once the blood begins to cool. The magnitude of occasional changes in blood pressure and heart rate varied considerably between patients and appeared to have no direct relationship to the age of the patient and the type of the heart disease. Venous pressure rose on cooling and remained elevated. As the blood cools, the same constrictive effect seen in the arteries occurs in the veins. Under those circumstances the flexibility of the venous reservoirs is lost and volume changes are reflected in rising pressure. It is not clear why venous pressure remains high during rewarming when cardiac output is actually increasing. During total circulatory occlusion, the blood pressure fell, the heart rate (after neostigmine injection) slowed abruptly, and venous pressure at first rose and then fell in some patients. After return of circulation, an immediate overshoot of blood pressure occurred, while venous pressure dropped abruptly. During rewarming, all the circulatory signs returned to within normal limits at 34 C (93.2 F). Cardiovascular reflexes governing the circulation appear to be intact and adequate in man undergoing hypothermia in the range of 26 to 31 C.

The Utilization of Fog as a Therapeutic Agent. R. M. Tovell and D. M. Little Jr. Anesthesiology 18:470-479 (May-June) 1957 [Philadelphia].

Ninety patients with various disorders of the respiratory tract such as laryngotracheobronchitis in 63, poliomyelitis in 20, asthmatic bronchitis in 2, pneumonitis in 3, and edema of the larynx in 2 were treated by the use of a form of humidification provided by the installation of a natural fog generator in a full-sized patient room. Treatment periods ranged from less than a day to almost a month. Fog consists of finely divided water droplets in supersaturated air and is formed by the condensation of these very small air-borne droplets from the vapor state. These droplets reach the terminal bronchioles and penetrate to the alveoli themselves. The supersaturated atmosphere provides more moisture in terms of grains of water per pound of dry air than other methods of humidification in common clinical use; 10% excess moisture or supersaturation in the temperature range of 70 to 75 F (21 to 24 C) is the average obtained in the "fog room." The fog room thus provides a supersaturated atmosphere, at comfortable and controllable temperatures, in an area that is large enough to permit adequate nursing care and to prevent the development of a sense of claustrophobia in the patient.

Results obtained with the use of "cold" humidification as treatment for acute laryngotracheobronchitis have been particularly satisfactory, since it has been possible to prevent secretions from drying, becoming tenacious, and further obstructing respiration. It has also seemed probable that in some patients it has been possible to avoid performance of tracheotomy because of the therapeutic results obtained in the fog room. The importance of humidification for the patient with a tracheotomy has been impressively emphasized by the group of patients with poliomyelitis requiring care in a respirator located in the fog room. Therapy of a supersaturated atmosphere helped to prevent the sinister complication of crusting of secretions in the air passages of these patients. The control of temperature provided in the fog room proved to be a significant asset in the management of poliomyelitis, particularly when the hyperthermia inherent to the pathological process was accentuated by high environmental temperature occurring during summer months when the disease was prevalent.

This latter experience formed the basis for regulating the natural fog generator to produce a cold, relatively dry atmosphere and to utilize it to combat hyperthermia and to produce a moderate hypothermia (91 or 92 F) in 5 neurosurgical patients with midbrain damage caused by head injury, the postoperative effect of surgical intervention, and, in 1 patient, encephalitis of unknown origin. Results suggested that prolongation of life has been facilitated thereby in several of these patients.

Jaundice Following Small Amounts of Chlorpromazine. H. Zarowitz and I. S. Friedman. New York J. Med. 57:1922-1924 (June 1) 1957 [New York].

While many reports have appeared which stress the production of jaundice after chlorpromazine has been used for a period of time in large doses, the authors of this paper noted that jaundice may appear even after small amounts have been taken. The histories of 3 patients are presented in whom jaundice developed after doses of 45, 250, and 200 mg. In none of these patients was there any evidence of preexisting liver disease. The third patient had had a gallbladder operation 30 years previously but showed no signs of biliary tract disease during the ensuing years until her present illness after chlorpromazine had been administered. All the liver function studies indicated regurgitant jaundice. A survey of the literature revealed 2 other reports stressing the relation of jaundice to small doses of chlorpromazine.

Recently it has become an almost routine procedure in some institutions to administer chlorpromazine parenterally in order to diminish preoperative sedative requirements and postoperative nausea and vomiting. The effective initial dose seems to be 25 to 50 mg. It is evident that, since small doses are capable of producing jaundice, patients who have undergone abdominal surgical procedures and, more particularly, biliary tract manipulation might develop jaundice from the chlorpromazine rather than from the operation. In addition, confusion might arise in those instances of jaundice where both chlorpromazine and blood or plasma have been administered.

PUBLIC HEALTH

Clinical and Epidemiological Observations on Dengue Fever in Queensland, 1954-1955. R. L. Doherty. M. J. Australia 1:753-756 (June 1) 1957 [Sydney].

An outbreak of dengue occurred in the area served by the Innisfail Field Station of the Queensland Institute of Medical Research from March, 1954, to May, 1955. The clinical and epidemiological features of 75 patients referred to the field station whose disease was diagnosed as dengue fever are analysed. The disease presented as a febrile illness lasting from 2 to 7 days, with headache and muscular pains and with marked prostration in the more severe cases. Lymph node enlargement was the commonest abnormality. Rash, bradycardia, and biphasic temperature chart were seen in a number of cases, but many had no specific clinical features. The demonstration of complement-fixing antibodies in significant titer against antigens of the dengue group (particularly Murray Valley encephalitis antigen) gave support to the diagnosis in from 33 to 50% of the patients tested. Blood from 29 patients was inoculated into mice, but no virus was isolated. The much higher relative incidence of dengue fever in one over another locality is ascribed to the presence in the one of rain tanks and rubbish dumps, which provide facilities for the multiplication of Aedes aegypti. The city of Brisbane, from which A. aegypti is now absent, escaped the outbreak. This is noteworthy, as Brisbane had a high incidence in past invasions of Queensland by dengue.

Salmonellosis in Massachusetts: A Sixteen-Year Experience. R. A. MacCready, J. P. Reardon and I. Saphra. New England J. Med. 256:1121-1128 (June 13) 1957 [Boston].

An analysis of 2,625 salmonella organisms other than salmonella typhi recovered during a 16-year period, from 1940 to 1955, in Massachusetts, revealed 50 different types. S. typhimurium was the most frequent of all species recovered, followed by S. montevideo, S. newport, S. oranienburg, S. paratyphi B, and S. bareilly. The recoveries of these Salmonella organisms rose to a peak in August, when they more than doubled those made in the low month of Febuary. A substantial number of recoveries, however, vas made in all months. The seasonal variation of S. yphi recoveries closely paralleled that of the other ypes. The infection rate was higher in children than n adults and was especially high in the first year of ife. The gastroenteritis syndrome of diarrhea with or vithout fever was present in 70% of all patients and he typhoidal septicemic syndrome in only 6%. With S. paratyphi B these 2 syndromes were about equally requent. The typhoidal septicemic syndrome was present in 55% of the patients with S. choleraesuis nfection and the gastroenteritis syndrome in 26%. The infection rate from Salmonella organisms other than S. typhi was 1.4%; in the age group of 60 years or older it rose steeply; S. choleraesuis gave the highest death rate, 16%; the death rate for S. typhi was 8%.

Salmonellosis has not yet been effectively controlled in Massachusetts. The number of infections has increased from 58 to 393 since 1950. In the whole country the reported number of cases of salmonellosis increased from 1,233 in 1950 to 5,447 in 1955. It is widely held that animal products such as meat and eggs are the major sources of the infections among human beings. Measures to ensure their bacteriological safety must be, therefore, developed, as has already been accomplished with milk. During the 16 years of this study the number of carriers increased from 9 to 24; 12 carriers left at the end of 1955: 6 died, 4 had moved away from the state of Massachusetts, and 2 had ceased to be carriers (1 after gallbladder removal and the other, who had been a proved carrier for 2 years, spontaneously).

The number of S. typhi recoveries has continued to decrease, going from 99 in 1940 to 15 in 1955. The number of female patients who became carriers appeared to be higher than that of the males. Eleven salmonellosis outbreaks occurred during the period in which this study was carried out.

Clinical Manifestations of Salmonellosis in Man: An Evaluation of 7,779 Human Infections Identified at the New York Salmonella Center. I. Saphra and J. W. Winter. New England J. Med. 265:1128-1134 (June 13) 1957 [Boston].

A total of 7,779 human infections, exclusive of infections caused by Salmonella typhi and cultures from military personnel, were studied at the New York Salmonella Center between 1939 and 1955. Nearly 90% of the infections came from 5 eastern states, but almost all states were represented by some cultures. More than 300 infections were identified in cooperation with laboratories in Europe, Asia, Africa, Australia, and South America. Gastroenteritis was the most frequent clinical sign, occurring in 5,312 patients (68.3%). It ranged from the mildest ambulant forms to a most severe cholera-like form, associated with rapid dehydration, convulsions, and death, or a dysentery-like form with bloody, slimy discharges and tenesmus. Nausea, abdominal cramps, anorexia, and vomiting were frequent. The gastroenteric signs started mostly 12 to 48 hours after the ingestion of contaminated food and lasted for 1 or 2 days. High and persistent fever was rare. Bloody diarrhea was frequent in young children but rare in adults. Signs of a generalized infection, with high fever of a typhoidal or septic type, or focal manifestations such as meningitis or pneumonia or both developed some days or weeks after complete recovery from gastroenteritis. These manifestations were more frequent in infections with S. paratyphi B and, particularly, in those with S. choleraesuis. Excretion of Salmonella organisms in feces or sometimes in urine continued for weeks or months after the return of normal bowel function. All Salmonella types were found to be capable of producing septicemic or typhoid-like fever. S. choleraesuis was chiefly responsible for the septicemic type. S. paratyphi A and B and S. panama most frequently produced typhoid-like signs, which were milder than those of typhoidal fever caused by S. typhi. Focal manifestations were the predominant clinical signs in 572 patients (7.4%).

The acute inflammatory processes were associated with the gastrointestinal tract in 146 patients. Patients were often reported in this connection as operated on for clinically typical acute appendicitis, but with no pathological findings except for an acute enteritis of the lower ileum. S. typhimurium was frequently the causative agent. Abscesses occurred in 136 patients in any part of the body; the precise origin of the underlying inflammation could not be determined in a number of these pus formations. Infection of the respiratory system occurred in 85 patients and was frequently associated with high fever and a fatal outcome. Meningitis was observed in 77 patients with a great variety of Salmonella organisms recovered from the spinal fluid; almost all these patients were infants, a few days or weeks old. Osteomyelitis occurred in 59 patients, with almost all bone structures involved. There were urinary infections in 49 patients, frequently with signs of cystitis. Subacute bacterial endocarditis occurred in 20 patients of all age groups; all these patients died. A total of 318 cases (4.1%) of the clinical and subclinical cases of salmonellosis were fatal. In 172, infection was due to S. typhimurium and S. choleraesuis.

Of all the cultures submitted, 15.5% came from healthy carriers. Half of these carriers had previously suffered from gastroenteritis. Others had had close contact with patients with Salmonella infection or had partaken of contaminated food. A considerable number of carriers were followed for several years, without any change in their condition, although many of the infections cleared up spontaneously. Some of the carriers were extensively treated with the antibiotics that were found active in vitro against the organism; the results were disappointing. The high incidence, morbidity, and fatality rate of group C infections, particularly those due to S. choleraesuis, is emphasized, and the inclusion of the C antigen in the active immunization process is recommended.

BOOK REVIEWS

Practical Gynecology. By Walter J. Reich, M.D., F.A.C.S., F.I.C.S., Attending Gynecologist and Section Chief, Fantus Clinics of Cook County Hospital, Chicago, and Mitchell J. Nechtow, M.D., F.A.C.S., F.I.C.S., Associate Attending Gynecologist, Cook County Hospital and Fantus Gynecologic Clinic. Second edition. Cloth. $12.50. Pp. 648, with 284 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W.C. 1, England, 1957.

This book is primarily for the general practitioner. It contains a common-sense discussion of psychosomatic gynecology and an acceptable chapter on infertility; it is well illustrated with line drawings and photographs and has, at the end, 68 beautiful colored reproductions of such things as cervical lesions and vaginal smears; but much of the rest of the book is aimed at about the level of a third-year medical student. It is incomplete, as it contains no mention of endometrial hyperplasia. There are no references to the literature. There is practically no discussion of treatment, and much of what there is, is dangerous. The following are examples. "Ovarian cysts will usually respond to doses of the order of 2,000 r spread over one or two months." Carcinoma of the vulva "is usually a squamous cell carcinoma and can be controlled by irradiation therapy as any other skin carcinoma." The authors persist in using the term and concept of "imperforate hymen." The book needs a thorough revision by some critical and informed person. It is published on glossy paper. There is a fairly adequate index. It is attractively and carefully printed.

Magnetic Removal of Foreign Bodies: The Use of the Alnico Magnet in the Recovery of Foreign Bodies from the Air Passages, the Esophagus, Stomach and Duodenum. By Murdock Equen, M.D., F.A.C.S., Chief of Staff of Ponce de Leon Infirmary, Atlanta, Ga. Cloth. $4.50. Pp. 94, with 119 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1957.

In this small book the author has discussed his experience in the recovery of 228 foreign bodies from the air passages, the esophagus, stomach, and duodenum by the use of the Alnico magnet. Writing in an informal and conversational style and using abundant illustrations, the writer not only describes his techniques but points out the disadvantages, contraindications, and precautions and discusses those cases in which the magnet was used without success. The chapters deal with history, the technique of using the magnet, other apparatus required, air passages, esophagus, stomach, duodenum, and the limitations of the magnet. Illustrative case reports are included. This book should prove informative to many groups but particularly to the otolaryngologists, roentgenologists, and thoracic surgeons.

BCG Vaccination Against Tuberculosis. By Sol Roy Rosenthal, M.D., Ph.D., Director, Institution for Tuberculosis Research of the University of Illinois, Chicago. With sections by Dr. Camille Guérin, Dr. Bernard Weill-Hallé, and Dr. Arvid Wallgren, Professor of Pediatrics and Head of Pediatric Clinic, Royal Caroline Institute of Medicine, Norrtull's Hospital, Stockholm. Cloth. $7.50. Pp. 389, with 43 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. B. Lippincott Company, 4865 Western Ave., Montreal 6, Canada, 1957.

BCG vaccination against tuberculosis is accepted, with few exceptions, in virtually every country in the world, and it is estimated that over 100 million people have been so vaccinated. In the United States, BCG vaccine is widely used but on a small scale. The American Trudeau Society, Public Health Service, and the Council on Drugs of the American Medical Association recommend its use for persons unavoidably exposed to tuberculosis and for groups considered to have inferior resistance and who live in communities with unusually high mortality from this cause. Despite these recommendations, most persons in the recommended groups have not been vaccinated.

This volume is directed toward the medical profession and allied groups with the hope of clarifying the problem. It does not attempt to review all the vast literature. The subjects considered are immunity in tuberculosis; vaccines other than BCG against tuberculosis; history of BCG; cultural characteristics, morphology, and staining properties; dissociation and variation of virulence or attenuation; reproduction; host response; culturing and preparing BCG vaccine; standardization; preservation by freeze-drying; routes and methods of administration; the tuberculin test in BCG vaccination; resistance in animals and man; virulence in animals; untoward reactions and virulence in man; vaccination in those infected with tubercle bacilli; and tuberculosis control and BCG vaccination. The author concludes that tuberculosis still remains a major health problem in the United States. In this country, where tuberculosis control programs exist on a large scale, BCG vaccination can play an important role in further diminishing the incidence of the disease. Whether or not you agree with all the conclusions drawn, this volume is well worth reading.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

DIABETES FOLLOWING CORTICOSTEROIDS

To the Editor:—*Can treatment with corticosteroid drugs (cortisone and prednisone) ever produce diabetes mellitus in an individual? Could this diabetes persist even after cessation of treatment?*

M.D., Illinois.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—In an hereditarily predisposed individual, corticosteroids may be a factor in the production of diabetes. Hyperglycemia and glycosuria, seen during therapy in an individual not predisposed to the disease, disappear with cessation of treatment.

Answer.—The glucocorticoids, such as cortisone and prednisone, may reduce carbohydrate tolerance. When given to experimental animals, the glucocorticoids affect fat, protein, and carbohydrate metabolism and promote gluconeogenesis, hyperglycemia, and glycosuria. They may cause negative nitrogen balance unless adequate protein is supplied.

The evidence at present seems to be that in patients who already have borderline glucose tolerance diabetes mellitus may be precipitated by glucocorticoid therapy. It must be pointed out that the renal threshold for glucose may be lowered by glucocorticoids and a temporary renal glycosuria may result. Usually, if carbohydrate tolerance has been depressed by glucocorticoids, it returns to previous levels if therapy is terminated. True diabetes mellitus, however, can at least be precipitated in predisposed persons by cortisone and similar steroid hormones. The diabetes may persist after cessation of administration of such hormones.

REFLEX VOMITING AFTER FATTY MEAL

To the Editor:—*Why does a meal with excessive fat cause nausea or nausea and vomiting in so many patients who otherwise are perfectly healthy?*

M.D., California.

Answer.—Nausea and vomiting are basically reflex in nature regarding the stimulus. Unless a conditional reflex has been established in the condition described, the stimulus does not arise in the higher centers. If vomiting occurs rather promptly after ingestion of a meal high in fat, the initiating stimulus may act on receptors in the oropharynx which may be particularly sensitive to fat. It may be recalled that swallowing a tablespoon of any kind of fat is normally rather difficult and likely to cause nausea and vomiting. If the response occurs a considerable time after ingestion of fat (half an hour or more), it is likely that afferent vagus fibers of the stomach are stimulated. This could be brought about by an exaggerated enterogastric reflex which might be reinforced by a sensitive enterogastrone mechanism, either or both of which could lead to gastric stasis with subsequent nausea and vomiting.

TREATMENT OF OTITIS EXTERNA

To the Editor:—*What is the advisability of using hydrocortisone—ointment, cream, or suspension—in the treatment of otitis externa? Is there any other new treatment?* *M.D., New York.*

Answer.—The treatment of otitis externa truly taxes the ingenuity and resourcefulness of the physician and the patient alike. Before arriving at a diagnosis with idiopathic otitis externa, specific skin diseases, such as seborrheic dermatitis and psoriasis, should be carefully ruled out. Cultures and sensitivity studies should be performed before any type of antibiotic therapy is instituted. Occasionally a direct smear of the exudate from the external canal, stained with either Wright's or Giemsa stain, will give the physician some idea as to the predominant organisms, and sometimes it is even more helpful than the cultures themselves. It is sometimes difficult to determine, after one has isolated organisms by culture, whether these organisms are actually producing a secondary infection or whether they just happen to be living on eczematized skin. It should be kept in mind that the high humidity which exists in the external canal surely is conducive to the growth of bacteria, especially if the canal is eczematized.

After one has arrived at a diagnosis of idiopathic otitis externa, one then has to choose the most appropriate preparations for beginning treatment. The choice of vehicle for the medicament to be employed is important. In general, the same rules follow in choosing the vehicle as apply for patients with eczematous dermatitis in other parts of the body. When the patient's otitis is very acute, edematous, weeping, and crusted, the vehicle of choice is either an aqueous solution or a lotion containing the drug. As the otitis becomes less acute, one may then employ oil-in-water emulsions as vehicles. As it becomes still less acute,

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

water-in-oil emulsions may be employed. The best antieczematous drug is hydrocortisone and its derivatives, specifically, fluorinated hydrocortisone. Some cases appear to respond best to the fluorinated compounds; others respond better to the plain hydrocortisone. Hydrocortisone is employed in percentages varying from 1 to 2.5%, and the fluorinated compounds are employed in percentages varying from 0.1 to 0.25%. The same percentages may be used in the ointment bases described above.

When the patient's dermatitis extends far into the external canal and even encroaches on the drums, it is better to drop the lotion into the ear canal rather than to attempt the fruitless task of trying to apply an ointment into this area with the finger. One or two drops of the hydrocortisone or fluorinated hydrocortisone lotion may be used three times a day. On the parts of the external canal which are accessible to the finger, the lotion or ointment may be applied three to five times a day, with the finger rubbing the lotion or ointment (as the case may be) in well. Caution should be taken against applying layers of ointment too thickly. The lotion form of hydrocortisone preparations in the form of drops may be used at the same time that an ointment for the part of the canal accessible to the finger is used. The patient should file his nails smooth, so that the canal will not be damaged by scratching. If a secondary infection is definitely present, appropriate antibiotics are chosen and employed in the same type of vehicle as the hydrocortisone preparations mentioned before. For infections caused by Pseudomonas organisms, polymyxin B is preferred; for micrococcic (staphylococcic) infections, one of the tetracycline preparations is used. Recent studies have revealed that neomycin sensitivity in otitis externa is a definite possibility, so that long-continued use of neomycin in the external canal should be avoided. Patients with otitis externa seem particularly apt to develop neomycin sensitivity.

HEADACHE DUE TO ALLERGY

To the Editor:—*Is it possible for a person with an allergic history to have headaches over the entire head area? Could allergy also cause the appearance of "spots" before the eyes?* *M.D., Illinois.*

Answer.—It is possible for a patient with an allergic history to have headaches over the entire head area; however, in most instances allergy of the nose and nasal sinuses causes a pain which is located chiefly in the forehead and across the bridge of the nose. It may be more on one side than on the other but may be on both sides at the same time. It is rather unusual for patients who are allergic to have pains on top of the head or in the back of the head. Those pains are usually associated with tension headaches. This consultant does not believe that allergy leads to "spots" before the eyes. Ophthalmologists advise that in older patients these spots come naturally and stay permanently.

FOLLOW-UP OF X-RAY SURVEYS

To the Editor:—*Have any studies been made to suggest how many cases of active tuberculosis might be overlooked when bacteriological tests are not included as part of the routine follow-up of all miniature x-ray survey films interpreted as "lung lesions"? Is it not common practice to dismiss such cases if a single large film, though perhaps showing pathology, does not give the impression of activity?*

M.D., California.

Answer.—To dismiss a suspect tuberculous condition on the basis of one film is poor medical practice. Any significant lesion on a chest film deserves additional study, which should also include a study of the sputum and skin tests with tuberculin, histoplasmin, and coccidioidin. The key word, of course, is "significant." If the lesion is a small, very dense calcification or a slight blunting of the costal angle, it should not be considered as significant.

Mass x-ray surveys should have an adequate clinical center to which all suspects can be referred, and in hospital surveys it is assumed that such follow-up will be available within the institution. On the other hand, there are cases of large excavating lesions where the probability of tuberculosis is so great that the follow-up is urgent, and such patients should be kept from circulation until the diagnosis is reached.

SPERMATOGENESIS

To the Editor:—*A man, aged 27 years, suffered a severe electric shock when 7,600 volts of electricity ran through his body as an electric cable touched a hoist crane where he was standing. He received electric burns of both hands and feet, and there was a small ulceration on the glans penis. When the patient was examined a month later, the penis showed healing of the ulcer, with scarring and redness. The testes are small but normal, and the patient states that they have always been small. There are no remarkable findings in the epididymis and the prostate. A sperm count taken a year and a half ago was 85 million per cubic centimeter of semen, with 20% motility at 1 hour and 5% motility after 24 hours. Semen analysis about six weeks after injury gave a count of 9 million sperms per cubic centimeter, with an occasional motile sperm noted at one hour and all dead at two hours. A repeat semen analysis two months after injury gave a count of 6 million sperms per cubic centimeter, with no motility at one hour. Is it possible for the electric shock to have caused this severe oligospermia?*

John M. Schultz, M.D., Miami, Fla.

Answer.—Very little has been published on the effect of high voltage on spermatogenesis. Opinions among investigators in the field of infertility vary sharply. Agreement appears to be confined to the conclusion that further investigation is necessary. This patient was apparently infertile prior to the accident.

Semen examination some 17 months earlier, presumably done because he had failed to father a child, had shown that he had depressed fertility. His testes were then small, and they did not become smaller after the accident. Biopsy of a testicular specimen may throw some light on the subject. Without this study, a plausible explanation may be that the patient has a progressive deterioration of fertility, the exposure to the high-voltage current being only incidental.

RHEUMATIC FEVER PROPHYLAXIS WITH PATIENT ALLERGIC TO PENICILLIN

To the Editor:—*What is the latest treatment of rheumatic fever in the case of a patient who is allergic to penicillin? H. V. Weems, M.D., Sebring, Fla.*

Answer.—It is assumed in the query that "treatment" implies prophylaxis, because one does not actually treat a patient with active rheumatic fever with penicillin or any other antibiotic. Although prophylaxis is best achieved with dibenzyl penicillin administered by injection or with orally administered penicillin, other antibiotics can be used. The council on rheumatic fever and congenital heart disease of the American Heart Association has recommended penicillin as first choice, sulfadiazine as second choice, and other antibiotics, such as tetracycline, as third choice. It would seem, therefore, that in this particular patient sulfadiazine should be used. The dose is 1 Gm. per day, given in a single dose either immediately after breakfast or before retiring at night. The greatest experience has been accumulated in prophylaxis of rheumatic fever with either penicillin or sulfadiazine. It is quite possible that other antibiotics, such as tetracycline, might be used effectively in prophylaxis. There are some reports in the literature of such use. However, since there are so many long-term studies already reported on the effectiveness of sulfadiazine, it is advised that sulfadiazine be used in this case.

TREATMENT OF TOE ULCER IN A DIABETIC

To the Editor:—*A diabetic, under control for about a year, has an ulceration, half a centimeter in diameter, above the proximal phalanx of the big toe. All conservative measures have failed. Please advise as to treatment.*

Frederick W. Gebhardt, M.D., Columbia, Ill.

Answer.—In the case of the patient described, the first step is to obtain an x-ray of the foot. If there is no osteomyelitis, the following course of treatment is suggested: 1. The patient should be put to bed at complete rest. 2. A culture of the secretions from the ulcer should be made, preferably after a period when the patient has not had antibiotic therapy. 3. Antibiotic therapy should be given as suggested by the organism present and suggested by sensitivity tests. Such antibiotic therapy must be carried out for many weeks and should be continued indefinitely, as long as there is evidence of healing. During the time of therapy diabetic management, which is as strict as possible, is necessary. This includes an adequate and nutritional diet and insulin enough to make sure that the patient has no glycosuria. 4. Some vasodilator drug should be given during the time of bed rest. Priscoline or Arlidin are two which may be used. 5. Local measures should be kept at a minimum. No ointments are suggested. The ulcer should be kept covered with a thin layer of gauze only, and the foot should be soaked once daily in a solution of 1:5000 potassium permanganate or some similar disinfectant.

In the presence of some circulation to the foot and without osteomyelitis, many of these ulcers heal on the above regimen if it is followed for a long enough time. This may be several months. In the presence of osteomyelitis, especially if there is moderate to marked reduction of the arterial supply of blood to the foot, midthigh amputation is indicated.

MOSQUITOES AS VECTORS OF INFECTIOUS HEPATITIS

To the Editor:—*Has it ever been demonstrated that mosquitoes can carry infectious (epidemic) hepatitis?*

Milton Zimmerman, M.D., Primavera, Paraguay.

Answer.—That mosquitoes might act as vectors of infectious hepatitis has never been demonstrated. In Central America, where there has been an abundant mosquito population, outbreaks of a disease have occurred which was originally thought to be yellow fever and which later proved to be infectious hepatitis. For this reason in areas where yellow fever is occurring and in areas where infectious hepatitis is present, virus studies (primarily neutralization tests for yellow fever) must be made to differentiate between these two diseases. Biopsies of liver tissue would be of assistance but are not always conclusive. Other insects, such as flies and bedbugs, have been suspected as carriers, but there are not sufficient grounds for any conclusion on this point. It would seem from the background of the various types of hepatitis that hepatitis following serum or blood transfusion (homologous serum jaundice) would be the type that would most likely be transmitted by insects. This disease, as is known, can be easily transmitted artificially.

The query is one which deserves much more research to prove or disprove whether mosquitoes can transmit infectious hepatitis. Pellissier (*Bull. Soc. path. exot.* 45:304, 1952) says of the role of mosquitoes in transmitting infectious hepatitis: "Transmission by mosquitoes, while not certain, appears very probable. (Mice were inoculated with a cross mixture of various species of mosquitoes; one mouse was said to have contracted the disease.) The inoculation experiments with isolated species of mosquitoes were not successful."

IMMUNIZATIONS AND SURGERY IN PATIENT WITH NEPHROSIS

To the Editor:—*The parents of a 9-year-old boy with a history of nephrosis say that they have been advised that the child should not be given any inoculations because of the possibility of a flaring up of the nephrotic condition. Assuming the nephrotic condition to be quiescent, what contraindications are there to the administration of poliomyelitis vaccine, triple boosters (diphtheria and tetanus toxoids and pertussis vaccine combined), and other vaccines? In addition, the child has a severe inguinal hernia on the left side. Is there any reason to postpone operation?*

D. L. Weinstein, M.D., Washington, D. C.

Answer.—In the opinion of this consultant there is no contraindication to the administration of poliomyelitis vaccine, triple boosters, or other vaccines to nephrotic children in remission. If the inoculations should cause a transient febrile reaction, albumin may appear in the urine for a few days, but this usually subsides quickly. In past experience, a recurrence of nephrosis has not been precipitated. If the child's general condition is good, the operation for inguinal hernia need not be postponed.

DAILY DOUCHING OF NOSE

To the Editor:—*Submucous electrocoagulation and clipping of the posterior ends of the inferior turbinates were done on a patient's nose for vasomotor rhinitis, with good results thus far. There has been a little dryness for years. Is it harmful to douche the nose daily with warm isotonic sodium chloride solution? Is it advisable to use one-half glycerin and one-half isotonic sodium chloride solution as a spray?*

M.D., Illinois.

Answer.—It is not improper to douche the nose daily with warm isotonic sodium chloride solution if it gives comfort. It is assumed that proper precautions are taken to avoid ear and other complications. If the 50% glycerin solution is not irritating or too drying, it is permissible to use it as a spray.

MOUTH TEMPERATURE AFTER SMOKING

To the Editor:—*Have any experiments been done concerning the temperature in the mouth of a patient when not smoking and the temperature of this same patient immediately after inhaling smoke from a cigarette, cigar, or pipe? Is there an increase in temperature, and to what degree, from the three methods of smoking mentioned above?*

Norman Glazer, M.D., Louisville, Ky.

Answer.—Smoking tests were carried out on five habitual smokers (cigarettes and pipe). The oral temperature was obtained before smoking and again 1 minute and 5 minutes after the completion of the smoking of a cigarette (5 to 7 minutes) and after 10 minutes of continuous pipe smoking. The greatest rise obtained was 0.1 F one minute after smoking. Apparently the amount of heat is too small to produce any significant change.

SURGERY FOR BILATERAL INGUINAL HERNIAS IN SIX-YEAR-OLD CHILD

To the Editor:—*A 6-year-old girl has had bilateral inguinal hernias for the past year. These are small (about the size of a hazelnut), and they protrude with coughing, sneezing, straining, or laughing. The child sometimes says, "Mama, my hernias are gurgling!" Is surgery considered unnecessary, advisable, urgent, or mandatory?*

Charles L. Concklin, M.D., Corpus Christi, Texas.

Answer.—In the opinion of this consultant an operation is advisable for this patient with bilateral inguinal hernias. At her age there can be no question of a spontaneous closure of the internal inguinal ring. The fact that the child notices "gurgling" when the hernias protrude implies that intestinal content enters the sac, and therefore the danger of incarceration is always present. The prudential course is to subject her to bilateral hernia repair during her school vacation.

ANTIGEN TEST FOR BRUCELLOSIS

To the Editor:—*Please supply information regarding the efficacy and the efficiency of Castañeda's antigen test for brucellosis. Is the test a simple procedure for a small laboratory?*

M.D., Michigan.

Answer.—The Castañeda antigen test for the diagnosis of brucellosis is a rapid slide test which is adjusted to detect the presence of serum agglutinins at or above a concentration of 1:100. It is best used during the early stages of acute brucellosis in man when its efficiency is high although admittedly somewhat inferior to that of the standard macroscopic agglutination test. The test is performed at the bedside or in the office with the whole blood of the patient (a procedure also feasible if the patient can visit the laboratory); otherwise the test is better performed with the patient's serum. The test is not intended to supplant the standard serum agglutination test but to save time in arriving at an early diagnosis.

The test's efficiency may lessen with later stages of disease, and its results may be equivocal if serum titers rise to high levels. The test is clearly most valuable when the operator is the physician who knows the history and physical findings of the patient. As with other forms of agglutination tests, primary efficiency is dependent upon the use of Brucella abortus cells with correct antigenic surface properties. Only the BAI standard antigen, or another abortus strain carefully and accurately verified to be its equivalent in reliability, should be used. The antigen should be prepared by a person who is competent in these matters. Excellent advice on how best to use it can be obtained from a paper by Castañeda (*J. Immunol.* 43:203, 1942).

THIRD PREGNANCY AND RH FACTOR

To the Editor:—*An expectant mother is Rh negative; her husband is Rh positive. Her first delivery was spontaneous at seven and a half months; the infant, weighing 4 lb. 3¼ oz. (1,900 Gm.), was jaundiced but did well under incubator care. Her second delivery followed a surgical induction done because of a rise of antibody titer from 1:20 to 1:28 during the eighth month of pregnancy. This infant weighed 5 lb. 14 oz. (2,700 Gm.) and was reported by the physician in attendance as "very ill from erythroblastosis, and four replacement transfusions were necessary." The patient at present seems to be doing well but has an Rh antibody titer of 1:512. What type of induction would be advisable, and when? Is cesarean section indicated? Is sterilization indicated? What are the criteria for replacement transfusions, and what is the method for calculating the amount of blood to be given?*

Morris Powell, M.D.,
St. Anthony, Newfoundland, Canada.

Answer.—Before specifically answering the questions raised in this query, some comments appear in order regarding the induction of labor in the second pregnancy of this patient, resulting in the birth of a premature infant. Today it is generally agreed that adding the insult of prematurity to the injury of hemolytic disease of the newborn (fetal erythroblastosis) considerably aggravates the prognosis and hence should not be deliberately brought about except in rare circumstances mentioned later on. It is conceivable, although not subject to proof, that, if the infant had been permitted to go to term, the disease, although present, might have been less serious than was reported. Furthermore, it must be mentioned that a rise of antibody titer from 1:20 to 1:28 appears to this consultant of doubtful significance, since it is well within the technical error of any titration method used for Rh antibody determinations.

A great deal of the prognosis for the present pregnancy depends on the zygosity of the patient's husband for the Rh factor. Information on this point may be obtained by testing the husband's Rh type, which may have to include tests for the hr′ and hr″ factors and tests of the Rh types of his parents, if available, and of the first child. If either of his parents or the first child is found to be Rh negative, this proves that the patient's husband is heterozygous Rh positive, and hence she can have Rh-negative children who will not be endangered by disease. Another important prognostic factor depends on the decision as to whether a rise in the Rh antibody titer has actually occurred during the current pregnancy, as is suggested by the titer of 1:512 reported now in contrast to the titer of 1:28 during the second pregnancy. However, only simultaneous titration of the two specimens carried out in the same laboratory can definitely prove this point. If a rise in antibody titer did occur, this would weigh heavily in favor of the fetus that is currently carried being Rh positive.

For the reasons mentioned above, one should not consider premature termination of the pregnancy by cesarean section or any other method of induction, merely because of the presence of a high titer of Rh antibodies. The only situation in which such steps are indicated concerns Rh-sensitized expectant mothers who have previously experienced fetal loss due to hemolytic disease of the (fetus and) newborn, with stillbirth occurring close to term, and whose husbands are most likely homozygous Rh positive. Statistics based on large series of cases show that, after an Rh-sensitized woman has had a stillbirth, in a subsequent pregnancy permitted to go to term she still has approximately one chance out of three of giving birth to an Rh-positive live child, amenable to successful treatment. Hence, even in such cases the prognosis need not be invariably hopeless. For the same reason, the mere fact that maternal Rh sensitization was responsible for one previous neonatal death does not appear to this consultant to represent an indication for sterilization.

Further recommendations for the current pregnancy are as follows: Determination of antibody titers should be repeated at monthly intervals, since a definite rise of the titer occurring during this pregnancy strongly suggests that the fetus is Rh positive. The patient should be permitted to carry to term. As soon as possible after birth, the Rh-type and direct antiglobulin (Coombs) tests should be done on the cord blood. If the infant is Rh positive and shows a positive Coombs test, a replacement transfusion should be carried out as soon as possible, even in the absence of any other abnormal clinical and laboratory findings. This recommendation is based on the fact that this condition represents latent hemolytic disease, which offers the best chance for complete recovery when treated as early as possible. The blood to be used must be Rh negative, preferably not older than three days, and must be compatible when cross matched with the serum of the infant's mother.

In general, indications for replacement transfusions include the following conditions: (1) abnormal clinical findings, such as hepatomegaly, splenomegaly, purpura, and local edema; (2) abnormal laboratory findings, such as hemoglobin level below 14 Gm. per 100 cc. and rising bilirubin level within the first six hours; and (3) history of a previously born sibling affected with hemolytic disease, followed by birth of another Rh-positive infant showing a positive Coombs test, even in the absence of clinical or laboratory evidence of disease. It is the last-named indication that has been used for the case under discussion. In order to bring about an efficient replacement of the infant's blood, at least 70 to 80 ml. of blood should be used per pound of body weight of the infant.

RH EFFECT OF TRANSFUSION SEVENTEEN YEARS AGO

To the Editor:—*Could a blood transfusion given to a mother 17 years ago have any effect on a newborn infant? The mother is Rh negative, and the father Rh positive; the child is premature and icteric.* *N. M. Freund, M.D., St. Louis.*

Answer.—A blood transfusion given to a mother 17 years ago could have an adverse effect on a subsequently born baby. At that time (1940) the discovery of the Rh factor had just been announced, so that Rh typing before giving a blood transfusion had not yet been introduced. Since six out of seven individuals are Rh positive, an Rh-negative person given a blood transfusion in 1940 would therefore be apt to receive Rh-positive blood and in this way could become sensitized to the Rh factor. When such a sensitized Rh-negative woman is mated later to an Rh-positive man, during pregnancy the Rh antibodies in her serum could pass through the placenta and attach themselves to the red blood cells of her Rh-positive fetus. The resulting baby could then be erythroblastotic. Whether this is true in the case concerning which inquiry has been made can be determined by testing the mother's serum for Rh antibodies and by doing a direct antiglobulin test on the baby's red blood cells to determine whether they are coated by Rh antibodies. Tests for Rh antibodies are essential in order to show that the mother's being Rh negative is not merely a coincidental finding.

CHRONIC CATARRHAL DEAFNESS

To the Editor:—*In the Queries and Minor Notes section of* The Journal *for July 13, 1957 page 1292, the answer says that the condition characterized by a conduction type of deafness with retracted drums, which was formerly known as chronic catarrhal deafness, has been shown to be otosclerosis.*

The consultant goes on to say that the tubal or tubotympanic catarrh which accompanies some respiratory infections may become chronic. He describes treatment to prevent this chronicity. It is good treatment and effective in a good proportion of these cases but not all. He says nothing about those cases, fortunately not very common, which progress from a "cold" to a severe and permanent deafness of the conduction type in six or eight weeks. I cannot imagine anyone calling this acute otosclerosis, but, if so, it seems as logical as to say that all cases of conduction-type deafness with retracted drums are due to otosclerosis.

If there is any reliable evidence that all cases of the condition formerly called chronic catarrhal deafness are actually otosclerosis, I have overlooked it and would appreciate references to the literature in which it is recorded. If the evidence supports it, a lot of us will have to change our ideas about the pathology and treatment of all acute and chronic inflammatory conditions of the ear.

H. P. Merrill, M.D.
458 S. Spring St.
Los Angeles.

The above comment was referred to the consultant who answered the original query, and his reply follows.—Ed.

To the Editor:—*The first paragraph of the original answer, starting with "Chronic catarrhal deafness," is inaccurate because of two accidental omissions. It should read as follows: "Chronic catarrhal deafness was formerly the exclusive diagnosis used for that clinical picture consisting of a conduction type of deafness with retraction of the tympanic membrane. The advent of the Lempert fenestration operation and the more recent stapes mobilization operation have revealed the proper diagnosis in many of these cases to be otosclerosis with bony fixation of the stapedial footplate in the oval window."*

In answer to the more recent query, otosclerosis and chronic catarrhal otitis media may coexist in the same ear at the same time (Kerrison: Diseases of the Ear, ed. 4, Philadelphia, J. B. Lippincott Company, 1930, p. 255). In chronic catarrhal deafness, fibrosis frequently results, with the formation of fibrous adhesions bringing about a fixation of the ossicular chain and/or an immobilization of the secondary tympanic membrane (Coates and others: Otolaryngology, Hagerstown, Md., W. F. Prior Co., Inc., 1956, vol. 2, chap. 2). If the adhesions do not involve any of these structures, little or no deafness will result. As for the treatment of the chronically deafened ear, owing to a catarrhal otitis media following a cold six weeks previously, catheterization and inflation of the middle ear and pneumomassage may be employed. If there is a stenosis of the eustachian tube, then eustachian bougienage may be carried out. Treatment of chronic catarrhal deafness has been generally disappointing. It is agreed that deafness of slight or moderate degree, coming on rapidly six weeks after a cold, could not be due to otosclerosis, because otosclerosis is a slow progressive disease rather than an acute one.

RESEARCH REVIEWS

From time to time there will be published in this section of THE JOURNAL *brief but not necessarily complete reviews of some of the newer clinical aspects of medical research and practice. This material is gathered specifically for* THE JOURNAL.—ED.

PAIN

Sir Thomas Lewis once said that pain is the interpretation that the cerebrum gives to certain sensory stimuli. Since then, much work has been done, but even today H. K. Beecher,[1] Harvard Medical School, Boston, concludes that "pain cannot be satisfactorily defined, except as every man defines it introspectively for himself." According to the same worker "no convincing demonstration has yet been given that the pain threshold is a constant from man to man, or from one time to another in a given man." It is difficult to measure pain in man and to substantiate the relationship between the pain threshold and the action of analgesic agents. In recent years, many attempts have been made by ardent workers in this field to measure pain and its relief in man quantitatively.

In experimental animals, reproducible results have been obtained by various workers. A method that has been widely used is the "hot-plate" technique in its various modifications.[2] A mouse is placed on a smooth metal surface kept at 55 C for not more than 30 seconds. It manifests discomfort by characteristic movements of the hind-limbs, and the time ("reaction time") of this effect is recorded. Analgesia is indicated by significant lengthening of this reaction time.

In a modification of the method of D'Amour and Smith, which was itself adapted from the work of Hardy, Wolff, and Goodell, rats are used.[3] The rat is held in a cylindrical holder of perforated zinc; its tail lies along a channel formed by two strips of asbestos. About 1.5 in. from the tip of the tail, a hole in the asbestos channel allows the heat from a small electric coil which is placed beneath it to rise and heat the tail. After an interval, the animal withdraws its tail from the channel with a sudden and characteristic flick. Again, this interval is timed and is called the "reaction time." The effect of various analgesic drugs can thus be compared. Modifications of this method have been introduced in recent years and are now used.[4]

Tests are also used in experimental animals that do not involve thermal stimuli. In the tooth-pulp method originally described,[5] holes were drilled into the pulp to allow electrical stimulation of the sensitive area. More recently, metal fillings have been inserted into holes drilled in the teeth and are electrically stimulated. It has been reported that this allows the determination of the threshold effect of analgesic drugs in animals.[6] Electrical stimulation of metal fillings in teeth has also been studied in man.[7]

The "writhing syndrome" is produced in mice by intraperitoneal injection of 2-phenyl-1, 4-benzoquinone; after 3 to 10 minutes, and lasting for more than one hour after the injection, the animals show characteristic intermittent contractions of the abdomen, twisting and turning of the trunk, and extension of the hind legs. Various analgesic drugs prevent or abolish this writhing.[8]

To show the analgesic effect of drugs that is not usually demonstrable by other tests, the inflamed foot of the rat has been used. The analgesic activity of various salicylic acid derivatives has thus been determined. It is claimed [9] that, on the basis of this test, three types of analgesics can be differentiated: (*a*) the peripheral antipyretic-analgesics of the salicylate type that have an analgesic effect in the presence of inflamed tissue; they reduce the elevated temperature of inflamed tissue but do not reduce the temperature of normal tissue, and they reduce edema; (*b*) the central antipyretic-analgesics of the *aminopyrine* type that have an analgesic effect whether or not an inflammatory reaction is present; they reduce the temperature of normal or inflamed tissue, and they reduce edema; and (*c*) the narcotic analgesics of the morphine or alphaprodine class that have an analgesic effect whether or not an inflammatory reaction is present; they do not reduce elevated or normal temperature, and they do not reduce edema.

It has been pointed out that animal tests measure partly a "reaction" to a painful stimulus rather than "perception" of pain and that some involve, at least in part, a spinal reflex that has nothing to do with perception of pain.[10] It appears that also in man [11] powerful analgesics primarily affect the "reaction" to pain rather than its "perception." It is thus important to reduce "anticipatory anxiety." It is difficult to study anxiety associated with the anticipation of pain and the effect of drugs on it in man experimentally. In the white rat, a method has been devised to test behavioral reaction to analgesics.[12]

Animal tests now in use are helpful in the preliminary screening of analgesic drugs when several methods are employed. This, however, does not always hold true. In the case of nalorphine (N-allylnormorphine), for instance, it was shown that this substance is a powerful analgesic in man [13] although this had not been demonstrated satisfactorily in animals. Interest in the study of nalorphine as an analgesic was revived by H. Isbell, U. S. Public Health Service Hospital, Lexington. Nalorphine is remarkable in having analgesic action without giving rise to addiction.[14] Its analgesic effect in man is approximately equivalent to that of morphine. Its subjective side-effects are partly like those of morphine, but at the analgesic dose level they are largely dysphoric. This makes its clinical usefulness as an analgesic doubtful when used alone. Combinations of nalorphine with other analgesics devised in the hope of reducing side-effects have proved impractical.

Another drug that has been studied clinically is anileridine [1-(beta-[para-aminophenyl]-ethyl)4-phenyl-4-carbethoxypiperidine]. Given intramuscularly, 40 mg. of anileridine is believed to be equivalent to 100 mg. of meperidine in the relief of postoperative pain.[15] As a supplement to nitrous oxide–oxygen anesthesia, 50 mg. of anileridine given intravenously is reported to be approximately equivalent to 100 mg. of meperidine in reinforcing anesthesia.[16] I. M. Riffin and his colleagues,[17] St. Vincents Hospital, Montclair, N. J., list the following advantages of anileridine: used in conjunction with nitrous oxide, it enables the anesthesiologist to maintain the patient in the "light zone of anesthesia" for major and minor surgery; the patient usually awakens on the table; there is smoother recovery; and regulation of tachypnea, which is frequent in the analgesic level, is easily attained with anileridine. They mention these disadvantages: controlled or assisted respiration is required during most of the operation, and a larger total dosage of succinylcholine is usually required in abdominal procedures. These workers state that in the control of postoperative pain, relief is obtained within 10 to 30 minutes after intramuscular injection and lasts for two to eight hours, with an average of five to six hours. All patients in this study had received phenobarbital, 30 mg. three times a day. Observations at Lexington have led to the belief that anileridine has addiction liability like that of morphine or meperidine.

Dihydrocodeine has been used as an antitussive agent in Europe for many years, but its analgesic effects have been reexamined in this country only recently.[18] Its analgesic action is of somewhat shorter duration than that of an equivalent dose of morphine. It has been given for the relief of moderate postoperative pain, and also in cases of severe postoperative pain, in a dose of 30 mg. per 70 kg. of body weight. When the dose of dihydrocodeine is raised to 60 mg., there is very little increment in pain relief. In this higher dose, dihydrocodeine depresses respiratory minute volume and produces other undesirable, morphine-like effects. This can be avoided with the 30-mg. dose, with which side-effects are hardly greater than with a placebo. Since the increase in pain relief from the 30-mg. to the 60-mg. dose is so small at the expense of a significant increase in side-reactions, it is thought to be preferable to give dihydrocodeine in the 30-mg. dose. When adequate analgesia cannot be obtained with this dose, another more potent analgesic may be given in place of dihydrocodeine.

Dihydrocodeine can be used in cases where more potent analgesics are liable to cause addiction. In equianalgesic dose, its addiction liability is greater than that of codeine but less than that of morphine.

In England, it has been reported recently [19] that dihydrocodeine depressed respiration considerably less than meperidine. In the United States, dihydrocodeine was given in a dose of 30 mg. to 50 patients in normal labor.[20] It did not cause cardiovascular or pulmonary depression in the mother or in the heart sounds of the fetus. There was less over-all fetal depression with 30 mg. of dihydrocodeine than with 100 mg. of meperidine. During the postpartum period, dihydrocodeine effectively relieved the discomfort of uterine contraction.

Another drug that has been studied in this country is ethoheptazine (1-methyl-4-phenyl-4-carbethoxyhexamethyleneimine). It is said to give analgesia without producing sedation or disorientation. It has no anti-inflammatory action. It has been used in the relief of moderate and moderately severe pain.

In a recent double-blind study,[21] ethoheptazine was given to patients with chronic pain due to arthritis, metastatic carcinoma, cardiovascular disease, neurological disorders, phantom limb after amputation, and nonunion of fractures. The analgesic effect of 100 mg. by mouth was compared with that of 600 mg. of aspirin, 30 mg. of codeine sulfate plus 600 mg. of aspirin, a placebo, and a combination of 100 mg. of ethoheptazine with 600 mg. of aspirin. Ethoheptazine combined with aspirin gave greater relief of pain than ethoheptazine alone.

Ethoheptazine with aspirin was as effective as codeine with aspirin. It is thought that ethoheptazine does not give rise to addiction.[22]

The methadone derivative levo-isomethadone (levo-4,4-diphenyl-5-methyl-6-dimethylamino-3-hexanone) given subcutaneously is thought to be equivalent in its analgesic effect to morphine. The optimal dose is 10 mg. It produces fewer symptoms than morphine, especially less nausea and vomiting. The decrease in oral temperature, oxygen consumption, resting respiratory minute volume, and respiratory response to 5% carbon dioxide is as great as with morphine.[23] The addicting properties of this drug are of the same order as those of morphine.

N. B. Eddy and his colleagues prepared acetylmethadols and described the results of their laboratory examination.[24] Alpha-acetylmethadols were tested in man by Keats and Beecher,[25] who concluded that the margin of safety was too narrow for clinical use. Given by mouth in a dose of 5 or 10 mg. three to five times a day, alpha-*dl*-acetylmethadol is effective against chronic pain but is not infrequently accompanied by morphine-like side-effects.[26] In the relief of postoperative pain, 50 mg. of alpha-*l*-acetylmethadol subcutaneously is thought to be equivalent to 10 mg. of morphine. Sometimes this drug has remarkably long-lasting effects and through cumulative action produces a dangerous comatose state resembling morphine poisoning. Alpha-acetylmethadols are addicting.

Another methadone derivative, dipipanone (*dl* 4,4-diphenyl-6-piperidino-3-heptanone) has been prepared as a racemate. Its analgesic effect has been tested in man in double-blind studies against chronic pain and against postoperative pain. For chronic pain and acute moderate pain, the optimal analgesic dose is thought to be 20 to 25 mg.[27] With doses of this order, side-effects have been minimal. The addiction liability of dipipanone is approximately equal to that of morphine.

Oxymorphone (dihydrohydroxymorphinone) has been tested clinically against chronic pain. It is a very potent analgesic; it has been estimated that 1.12 to 1.15 mg. is equivalent to 10 mg. of morphine.[28] The average effect in one series of cases was found to last 266 minutes when 1 mg. of oxymorphone was given and 277 minutes with 12 mg. of morphine. With equivalent dosage, the incidence of side-effects is about the same with oxymorphone and morphine. The addiction liability of oxymorphone is considerable.[29]

Another new analgesic that has been studied in man is propoxyphene (alpha-d-2-propionoxy-4-dimethylamino-1,2-diphenyl-3-methyl butane hydrochloride). A comparative study of this drug with codeine phosphate has been reported in THE JOURNAL recently.[30] The active isomer is now referred to as dextro-propoxyphene.

Dextro-propoxyphene by mouth is as effective as codeine, milligram for milligram, in the relief of chronic pain. Its side-effects in an oral dose of 65 mg. are, in general, less than with the same dose of codeine. The addiction liability of dextro-propoxyphene is considerably less than that of codeine.

Before a new agent is introduced, its addicting properties are tested. The initial estimation of addiction liability of analgesic drugs in the United States is based largely on the results of clinical studies on volunteers at the National Institute of Mental Health Addiction Research Center, United States Public Health Service Hospital, Lexington, Ky. The purpose of these addiction liability tests is to delineate the safety of a new agent relative to its possible beneficial effects. To supplement clinical tests, laboratory methods have been developed during the past seven years at the department of pharmacology, University of Michigan Medical School, Ann Arbor, under the direction of M. H. Seevers. Studies at this center have revealed that the rhesus monkey parallels man in important respects concerning development of tolerance to and physical dependence on the several classes of potent analgesic narcotics. As a result of these observations, new compounds are now sent to Ann Arbor for animal testing as coded samples and studied on a double-blind basis. This furnishes additional information useful in screening new compounds for their potential usefulness and a more accurate evaluation of their addiction liability. Before reaching the physician, every compound undergoes extensive clinical trial, since the laboratory data do not furnish information concerning pleasant subjective responses to these drugs, an aspect of the general problem that is highly important in the assessment of addiction liability.

In a discussion of analgesic drugs it is customary to exclude agents that act by removing the cause of the pain and agents that block pain impulses peripherally.[1] A method of reducing pain that has attracted increasing attention recently may be mentioned—hypnosis. Apart from its use in obstetrics and dentistry, hypnosis has found its way into the wider field of surgery. W. S. Kroger, Chicago Medical School, has made a film of a patient who underwent thyroidectomy without premedication or anesthetic. There was hardly any bleeding. Other operations, such as a cesarean section and hysterectomy, and biopsies of the breast for carcinoma, have been performed in a similar manner with the patient in hypnosis.[31]

Present methods of testing analgesic drugs in man and the study of pain relief obtained by hypnotic suggestion both point to the multiplicity of influences that may come into play clinically.

PREDICT NO HIGH MORTALITY RATE IN ASIAN INFLUENZA

Continuing to record and analyze information coming in from all over the country, the U. S. Public Health Service says there is a gradually increasing incidence of Asian influenza, but that no high mortality rate is in sight.

Early in September cases were being counted by the tens, or possibly the hundreds. By the end of September they were being counted in the hundreds of thousands, Mississippi alone having an estimated increase of about 76,000 within one week. Increasing school absenteeism was reported from Oregon, Colorado, Mississippi, and Texas, with a few California industries also showing more absenteeism.

The service plots the course of Asian influenza epidemics on the basis of reports received from state health departments. The following report is a typical summary of one week's findings in mid-September.

New York City reported 144 cases of influenza-like disease among arrivals from Europe, and 2 confirmed cases among city residents. At the same time the New York state department of health cited influenza-like illnesses in two camps of migrant workers from Alabama and Florida.

Among 250 fishermen in a small fleet off the southern coast of New Jersey 45 cases were reported, with two patients hospitalized with pneumonia.

In an Indiana college of 800, a total of 100 students were ill, and Illinois confirmed 2 cases from a number of sporadic attacks. Minnesota reported 35 clinical cases of influenza among 92 foreign exchange students arriving for the opening of the University at Minneapolis. Missouri and North Dakota had influenza cases scattered throughout the state, but with no confirmations as Asian influenza. Two adjacent counties in South Dakota had outbreaks, but here serological tests confirmed six cases.

Tennessee had no extensive outbreaks during August, but more than 500 sporadic influenza cases by the middle of September, with 15 confirmations. The disease is widespread in New Orleans and other parts of Louisiana, Arkansas has two confirmed cases, and members of the Florida University football team were stricken.

Migrant workers in Colorado also were affected, 125 cases among 545 individuals, Wyoming has had a few cases (unconfirmed), and New Mexico reports cases in 17 counties.

Among girls attending a California convention, the attack rate was an unusual 89%; one death in this group possibly attributable to Asian influenza, but otherwise almost no complications.

The Panama Canal Zone reports an unusually high incidence of upper respiratory diseases, involving 25 to 30% of the population, mostly adults, but efforts to confirm Asian influenza were not successful. In Puerto Rico, cases increased from 10 to 14,674 in less than a month. Says the health bureau: "Influenza has now spread throughout Puerto Rico."

INFLUENZA VACCINE MANUFACTURERS URGED TO FOLLOW STATE PRIORITIES

In an effort to insure that priority groups within a state will be the first to receive Asian influenza vaccine, the Public Health Service has asked the six manufacturers of the vaccine to follow priority recommendations of state and local advisory committees. Earlier, the manufacturers had adopted a voluntary system of allocating vaccine to states, based on the states' population.

The PHS and most state and local advisory committees have recommended generally that first vaccinations go to personnel in the health fields who will be needed to care for the sick and to patients who are a high medical risk, then to those needed to maintain essential community services, such as police and fire departments.

Requests that the priorities be carried further—to the state and local levels—were made to the manufacturers in letters from Dr. Leroy E. Burney, the surgeon general. "It is suggested particularly that you be guided to the maximum extent possible by the determinations of state and local advisory groups regarding which orders within states and communities should receive priority," Dr. Burney told the producers.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

The PHS announced that 19 states have reported formation of advisory councils to make priority recommendations and that some communities have set up councils to suggest distribution patterns on the city and town level.

"We believe the listing of essential personnel within a community can be done best at the community level," Dr. Burney explained to the manufacturers.

VA ADMINISTRATOR REGRETS DOCTORS' STAND ON HOSPITALIZATION

Veterans Administrator Harvey Higley regrets that the nation's feelings of "obligation and gratitude" toward veterans seems to have lessened noticeably in the last three years and that "some medical men" are "attacking medical care for veterans, with particular reference to those having non-service connected disabilities."

Addressing the American Legion convention, Mr. Higley declared in part:

"A mere decade ago, there were few who would challenge the legislation, in effect since 1924, which provides that a veteran with a non-service-connected disability has the right to enter a VA hospital if he cannot pay for the care elsewhere and if VA has a bed available.

"Yet, during the past three years, public statements by certain individuals and responsible organizations have contended that the non-service-connected should have no hospital benefits. Some medical men, who usually are keenly aware of the need for proper public relations, now apparently believe that the public no longer is greatly concerned with the veteran and his problems. And so they no longer hesitate to attack medical care for veterans, with particular reference to those having non-service-connected disabilities."

Mr. Higley also challenged the recommendation of the Bradley Commission that "The provision of constructive and adequate readjustment benefits, as a rule, should discharge the government's obligation to war veterans who have no service-connected disability."

The VA administrator asked whether this philosophy, "quite contrary to laws on the books for many decades," is to be today's thinking. The laws in question authorize the VA to hospitalize non-service-connected patients if there is a bed available and if the veteran cannot afford to pay. Mr. Higley believes Congress should clarify the situation. He explains:

"It seems to me that while there would be the cost of new construction, there would be no additional operating cost if we closed down the 3,906 unneeded tuberculosis beds . . . beds located where conversion to other use would not be practical . . . and replace them with 33-hundred other beds which would fill a great need . . . if the policy shall be to take care of sick and disabled non-service-connected veterans on the basis of our present laws.

"If the policy shall be not to take care of the non-service-connected, this should be frankly stated, so that others . . . States, counties and cities . . . may take up the load."

At one point Mr. Higley told the Legion:

"The essential elements of veterans' programs must be safeguarded. Weaknesses must be eliminated. We cannot afford to bury our heads in the sand and believe that everything is perfect . . . that these programs are sacred and therefore untouchable. There always will be critics, but let's not give them room for justifiable criticism."

AEC TO MAKE GRANTS TO MEDICAL SCHOOLS

Extending its present activities, the Atomic Energy Commission will make financial grants up to $250,000 to medical and other scientific schools to help them buy specialized radiation equipment and teaching aids in this field.

In outlining the program to encourage study of radiobiology and use of radioisotopes, the AEC said the aid would go to accredited schools of agriculture, veterinary medicine, and public health, as well as medicine, and to departments of biophysics and biology in schools and colleges.

Applicants must be nonprofit institutions, and with faculties qualified to conduct courses in nuclear technology as applied to the life sciences. The commission said in considering applications it will take into account the scope and objectives of the teaching program, the educational level of the program, and the number of students to be served.

The AEC already is sponsoring on-the-job training in its laboratories; special training in use of radioactive materials at Oak Ridge Institute of Nuclear Studies; fellowships in radiological physics, industrial hygiene, and industrial medicine; radiobiology training for high school science teachers; and radiobiology lectures conducted by AEC scientists in colleges and universities.

MISCELLANY

The Children's Bureau has asked three national groups for advice on the theme for the 1960 White House Conference on Children and Youth. They are the Council of National Organizations, the National Council of State Committees on Children and Youth, and the Interdepartmental Committee on Children and Youth. A national advisory committee on the conference, to be appointed by the President, will decide on the theme.

The Veterans Administration reports development of a tiny electronic meter for measuring blood pressure which "has opened a new field for understanding heart failure, shock, and other blood circulation disorders." The meter, about the size of the end of a match stick, is inserted into a vein, and may be gently pushed up and into the chambers of the heart and blood vessels of the lungs. The VA says it causes no pain or discomfort and that tissues of the veins are not damaged.

The National Red Cross has reduced its standard first-aid course from 18 hours of instruction to 10, in an effort to encourage attendance by those for whom time is a problem, particularly public employees. The Red Cross first-aid textbook also has been changed to reflect the shorter course.

CHANGING FORMS AND CAUSES OF PULMONARY INSUFFICIENCY IN PRESENT ERA OF MEDICINE

Israel Rappaport, M.D.
and
Edgar Mayer, M.D., New York

The incidence of insidious protracted development of pulmonary insufficiency is increasing, due to the delayed effects of pulmonary infections attenuated by chemotherapy, and to the cumulative effects of inhaled air pollutants. We are not dealing with complicating infections but rather, the signs and symptoms observed are the manifestations of pulmonary insufficiency itself. Pulmonary insufficiency implies disturbances in the autonomic functions of the structures at the bronchioloalveolar junctions. The exact nature of these functions is not known, but there is ample evidence that they are essential to normal distribution of ventilation and circulation throughout all parts of the lungs. The disturbance of this critical function implicated in pulmonary insufficiency may best be designated by the least prejudicating term of "bronchioloalveolar dysfunction."

AN OUTSTANDING new aspect of chronic pulmonary disease is the present rising mortality from cor pulmonale now chiefly attributed to chronic bronchitis and emphysema. Current experience indicates also a rising incidence of the latter and a change in the etiology of both. This present increase of bronchitis and emphysema comes from two new sources, namely, pulmonary damage from infectious diseases attenuated by modern chemotherapy and pulmonary damage from the effects of increased air pollution.

While the clinical picture leading to cor pulmonale is now often discussed in such terms as bronchial spasm, pulmonary insufficiency, and pulmonary hypertension, it is in general referred to as chronic bronchitis and/or emphysema. The latter are spoken of as specific disease entities and are looked upon as the primary causes of cor pulmonale by reason of mechanical obstruction to ventilation and circulation which they are presumed to create in the chest.

It is our belief that the clinical picture leading to cor pulmonale is now misinterpreted as chronic bronchitis and/or emphysema. This has resulted not only in confusion regarding the criteria of the latter —but also in a misunderstanding of the nature of pulmonary insufficiency as well as of causes of cor pulmonale. In this paper we are offering our interpretation of these conditions which we believe should help to clarify the present confusion.

Clinical Forms of Pulmonary Insufficiency

For over two decades we have observed a large number of patients with a variety of bronchopulmonary diseases, and in many of these we have been able to follow a progression to ultimate pulmonary failure with cor pulmonale. We have observed that, when these patients first began to show signs of pulmonary insufficiency, they all presented the same clinical picture commonly associated with bronchitis and emphysema, regardless of the widely different nature of the primary bronchopulmonary disease which led to the insufficiency. At first we accepted the prevailing view that this clinical picture was due to complicating respiratory infections. However, with the advent of chemotherapy, when it became possible to control complicating infections, we found that in most cases this had little effect upon the progressive clinical picture. We finally realized that we were not dealing with complicating infections but that the signs and symptoms observed were the manifestations of pulmonary insufficiency itself. Furthermore we observed that, in patients with reduced pulmonary reserve due to past bronchopulmonary diseases, complicating bronchial infections are more apt to arise after onset of pulmonary insufficiency than before. The temporary aggravation of symptoms and signs produced by the complicating infection is readily controlled by chemotherapy with little effect on the previous status of progressive pulmonary insufficiency.

Our clinical experience has led us to recognize three forms of this clinical syndrome: (1) the acute, which occurs in bronchial asthma; (2) the subacute, generally recognized as asthmatic bronchitis; and (3) the chronic, which is now commonly associated with bronchitis and/or emphysema. It has been a long-established fact that there exist fluent transitions between these three forms and that one can go over into the other.[1] The clinical features of all of these include signs and symptoms of bronchial dysfunction and of pulmonary hyperinflation. There is often variable predominance of one or the other, that is, the more fixed the overdistended lungs become, the less marked are the bronchial signs (wheezing, rhonchi) and vice versa.

Here we are concerned chiefly with the chronic form of the pulmonary insufficiency syndrome, which may develop on the basis of practically all pulmonary diseases that lead to loss of large parts of normally functioning lung parenchyma. It is particularly frequent in diseases that tend to involve the lungs diffusely, such as fibroses, granulomatoses, and other densely disseminated lesions, regardless of etiology. In most instances the progress of chronic pulmonary insufficiency appears clinically as an insidious and protracted process which may truly simulate chronic bronchitis for long periods of time until manifestations of the fully developed pulmonary insufficiency reveal themselves. Clinical experience also indicates that frequently this clinical syndrome may develop abruptly within a few weeks or months. This is apt to occur particularly in those of middle age after an acute pneumonic or pleuritic process or other medical or surgical condition, or with pulmonary complications of congestive, embolic, or metastatic nature. Here the symptoms of cough and expectoration with progressive dyspnea on effort appear rapidly and concomitantly. Whether of gradual or rapid development, this clinical picture reveals the imminence or presence of lack of pulmonary reserve.

The assumption that the clinical picture of chronic bronchitis and/or emphysema develops on the basis of bronchitis proper dates back to the preantibiotic era when bronchitis often became complicated by recurrent pneumonitic and suppurative processes which often led to destruction and/or fibrosis of much lung parenchyma. The latter then resulted in depletion of pulmonary reserve and so in pulmonary insufficiency which simulates chronic bronchitis and/or emphysema. In the present era of chemotherapy these severe complications of bronchitis proper are usually controlled and their serious sequelae are becoming less frequent. In cases where pulmonary insufficiency develops we must look for reasons of loss of pulmonary reserve other than that of bronchitis proper.

Misinterpretation of Chronic Bronchitis

The term bronchitis refers to an inflammatory process involving mainly the larger branches of the bronchial tree, and rarely extending to the finer bronchioles. This is an exceedingly common clinical as well as autopsy finding. It is a trivial disease for which people usually do not seek medical aid. Innumerable people, especially smokers, go through life indulging in rather than suffering from much cough and expectoration. The sputum consists of inflammatory products, is mucopurulent in character, and is often copious in amount. Chronic bronchitis in the form here described is especially frequent in people of advanced age and as such is not a disabling disease. Disabling chronic bronchitis is said to be due to airway obstruction leading to obstructive emphysema, although it has been a long-known fact that bronchitis is more often the result than the cause of emphysema.[2]

Misinterpretation of Obstructive Bronchitis and Obstructive Emphysema

[illegible] concepts of the interrelationship between bronchitis and emphysema are still based essentially on the old theory of Laennec, namely, that of obstructive bronchitis leading to mechanical overdistention of the lungs. Recently this has been modified to the theory of functional airway obstruction spoken of as "bronchial spasm" or "air-trapping" by disturbance of normal bronchiolar function. Even according to this theory, airway obstruction leading sooner or later to mechanical overdistention of the lungs is the key to the development of emphysema. Bronchitis and emphysema are thus assumed to be inseparably linked as essentially consecutive phases of one and the same clinicopathological process.

In practice this interpretation has led to confusing the criteria that distinguished chronic bronchitis from emphysema. It is not possible to tell when bronchitis ends or when emphysema begins. Characteristic of this confusion is the fact that the same clinical picture described by some as chronic bronchitis is designated by others as emphysema, each taking for granted the presence of one or the other condition as a complication.[3] Recently the term "bronchospastic disease" was proposed as a way out of this confusion.[4] However, as this new term is interpreted, it is just another name for the same old conditions and refers to variable combinations of bronchitis and emphysema on the same theory of pathogenesis.

It should be noted at this point that there is no factual evidence for the existence of bronchospasm in asthma, bronchitis, or emphysema, as is generally assumed. Nor is there any morphologic evidence of actual obstruction of the bronchial tree. Obstruction to airflow is inferred on the basis of the clinical features, the signs and symptoms of disturbed ventilation of pulmonary hyperinflation, and the viscidity of secretions. Clinically the distinction between obstructive bronchitis and emphysema is generally most difficult. Reliance is now put on functional testing, but the one test believed to be reliable for detecting the presence of emphysema, namely, determination of the over-all diffusing capacity, is still in the experimental stage.[5]

The current trend to discard the term obstructive emphysema in order to properly emphasize obstructive bronchitis as the primary disease is objectionable chiefly because of an implied association with bronchitis proper. There is nothing in the clinical entity of bronchitis as described above which implies that it usually leads to obstructive bronchitis. On the contrary, clinical experience indicates that obstructive bronchitis is more often the result rather than the cause of pulmonary emphysema. Certainly bullous change in emphysema must be considered conclusive evidence of bronchial obstruction, and both this and obstructive bronchitis are sequelae rather than causes of pulmonary emphysema. The presence of pulmonary emphysema is usually revealed first clinically by symptoms and signs due to bronchial obstruction. Extensive emphysematous changes may be present without clinical signs and symptoms which arise promptly upon advent of complicating bronchial obstruction.

The term obstructive emphysema refers to mechanical overdistention of airspaces behind obstructed airways permitting more ingress than egress of air. This is mostly a localized process caused by local involvement of bronchi. It occurs in a great variety of pulmonary diseases, mostly in the absence of emphysema. It often also occurs as a complication of emphysema when localized bronchial complications aggravate the enlargement of airspaces due to emphysema and produce localized bullous changes. In such cases, in the presence of the two combined forms of airspace enlargement, it is often impossible to separate the distending effect of obstructive bronchitis from the emphysema proper (structural defects) which we will discuss later. We have long emphasized the importance of recognizing the enlarged airspaces that are of mechanical origin and chiefly of a localized nature. For these we have proposed the term "airspace disorders." They are frequent clinical findings due to localized obstructive bronchitis, and they occur mostly in absence of emphysema and are often confused with and misinterpreted as such.[6]

From the foregoing it may be concluded that the clinical entity of chronic bronchitis does not imply bronchial spasm; that obstructive bronchitis and obstructive emphysema are clinically indistinguishable from one another; that obstructive bronchitis, contrary to general belief, is usually the effect of obstructive emphysema rather than its cause; and that the effects of obstructive bronchitis are better described as "airspace disorder," which is not to be confused with emphysema proper. Accordingly, if chronic bronchitis does not lead to obstructive bronchitis and if the latter does not lead to emphysema proper, then the question naturally arises as to what is the nature of the clinicopathological process leading to pulmonary insufficiency and cor pulmonale.

Manifestations of Pulmonary Insufficiency

The basis for the above-described confusion lies, we believe, in wrong interpretation of the manifestations of pulmonary insufficiency as those of chronic bronchitis. In fact we lack proper terms for these evidences of functional disturbance simply because we are ignorant of the true nature of the autonomic functions of the lung structures; also because disturbance of these functions, as revealed by symptoms and signs, is now misinterpreted as bronchial spasm and is assumed to be manifestations of obstructive bronchitis and emphysema.

Bronchioloalveolar Dysfunction.—We believe it to be a reasonable assumption that pulmonary insufficiency implies disturbances in the autonomic functions of the structures at the bronchioloalveolar junctions. The exact nature of these functions is not known, but there is ample evidence that they are essential to normal distribution of ventilation and circulation throughout all parts of the lungs. The disturbance of this critical function implicated in pulmonary insufficiency may best be designated by the least prejudicating term of "bronchioloalveolar dysfunction." The clinical symptoms and signs suggest that it includes increased bronchomotor and bronchosecretory activity manifesting themselves in chronic cough and expectoration. These symptoms are common with bronchitis, hence the confusion with the latter. Also bronchioloalveolar dysfunction is associated with progressive pulmonary hyperinflation which is at first reversible but later becomes irreversible. Progressive dyspnea then becomes a prominent symptom. The combination of irreversible pulmonary hyperinflation with bronchioloalveolar dysfunction is what we clinically recognize as pulmonary emphysema. In other words, clinically, emphysema becomes recognizable only by these

Other manifestations of pulmonary insufficiency mphysema, anoxia) are often found associated ith pulmonary hypertension, but their relationship only indirect. Perhaps that which is most closely lated to pulmonary hypertension is augmented ood flow from the systemic arteries. This suggests at systemic blood pressure transmitted mostly way of anastomoses between pulmonary and onchial arteries probably plays the key role in e origin of pulmonary hypertension.

Emphysema by loss of alveolar structures, pulmoary hypertension, and augmented blood flow from onchial arteries are three combined findings most equently observed in cor pulmonale. The usual terpretation has been that the sequence of events emphysema, hypertension, and finally augmented stemic blood flow. Recent observations in so- intralobar bronchopulmonary sequestration omalous systemic arteries of congenital lemonstrated the reverse sequence of nphysematous changes resulted from d supply. Similar emphysematous 1 observed also in lungs with hypo- e) pulmonary arteries leading to ronchial blood supply. In many ed the development of emphy- ormal lung areas under pleural which systemic blood flow in- reas so affected. Here too, we nce of events was most likely one a resulted from changes in blood

tulated that changes from pulmonary blood supply in any lung area may so bronchioloalveolar structures as to dis- functions and result in their eventual disappearance (emphysema) with all the previously discussed. Referring to these ted phenomena (clubbing, polycythemia) t publications, one of us [10] suggested that nomic function of the bronchioloalveolar es is regulated by a hormone carried to the ly by venous blood in the pulmonary arterial r bed. Interference with this autonomic funcver a large part of the lungs will manifest n all the evidences of pulmonary insufficiency ssed above. In final analysis then, cor pulle, too, would have its origins in pulmonary ficiency, i. e., loss of pulmonary reserve.

Recent Changes in Etiology

n the decade following the advent of modern emotherapy there became discernible a sharp op in mortality from acute and subacute bronchoulmonary infections, while at the same time there ccurred a sharp rise from cor pulmonale which has since then persisted. The connection between these events is obvious. More patients suffering from previously fatal bronchopulmonary infections now survive, later to become victims of pulmonary insufficiency leading to cor pulmonale. In fact this is true even of patients with far-advanced pulmonary tuberculosis whose life is prolonged by chemotherapy. In the latter, as well as in those with some destructive bronchopulmonary suppurations, there are demonstrable residues of fibrosis and emphysema which indicate the process leading to pulmonary insufficiency and cor pulmonale. A different effect of chemotherapy on inflammatory processes in the lungs was discussed by one of us [11] recently under the title "Chemotherapy and 'Vanishing Lungs.'" Clinical observations indicate that chemotherapy often produces emphysematous changes, probably by preventing dense fibrosis and favoring resolution and self-cleansing of the affected parts. We believe it is a reasonable inference that the same effect due to chemotherapy occurs to lesser degrees in a greater portion of cases which escape detection. Our observations lead us to infer that, in many cases in which bronchopulmonary inflammatory diseases have been attenuated by chemotherapy, subclinical forms of such acquired lung defects remain. By insidious protracted progress these become apparent much later, mostly in middle-aged patients presenting clinical features now generally recognized as chronic bronchitis and/or emphysema.

Even more characteristic of the present era is the prominent role of so-called irritative bronchitis from air pollution in the origin of chronic bronchitis and emphysema. In fact these two conditions are now increasingly spoken of as smokers' diseases.[12] Tobacco smoke is now looked upon as a most intense form of inhaled polluted air. Furthermore, "irritative bronchitis" resulting from air pollution has been prominently mentioned as a cause of pulmonary insufficiency in such diverse conditions as coal miners' dyspnea [13] and the attacks of fatal pulmonary insufficiency during the recent London smog.[14] In both instances we are dealing with injury to bronchioloalveolar structures which remains latent at the time of occurrence and later becomes manifest by subsequent cumulative effects. Clinical and pathological observations indicate that inhalation of injurious air pollutants may also cause damage to bronchioloalveolar structures that affects their function and results ultimately in pulmonary insufficiency.

It would appear then that in the present era of medicine there is an increasing incidence of insidious protracted development of pulmonary insufficiency due to the delayed effects of pulmonary infections attenuated by chemotherapy and to the cumulative effects of inhaled air pollutants. The number of people subject to the effects of these two new sources of pulmonary damage is very large when compared even with the present increased incidence of pulmonary insufficiency. Furthermore, there are very great individual differences in the evolution of the latter. In the majority of cases pulmonary insufficiency develops only with advancing age and depends obviously upon advent of the "involutional lung defect." In a minority of cases in which pulmonary insufficiency develops in young individuals, we must assume the previous presence of "developmental lung defect."

Summary

In the present era of medicine there is a notable increase in the incidence of pulmonary insufficiency leading to cor pulmonale. The clinical picture is usually misinterpreted as chronic bronchitis and/or pulmonary emphysema. We are dealing with the clinical manifestations of insidious protracted chronic pulmonary insufficiency consisting of the combination of bronchioloalveolar dysfunction (increased bronchomotor and bronchosecretory activity), pulmonary hyperinflation (emphysema) and augmented pulmonary blood flow from systemic circulation (anastomoses with bronchial artery). Pulmonary insufficiency is an indication of depleted reserves of normally functioning lung parenchyma. In the etiology of pulmonary insufficiency in the present era of medicine, an important role is played by two new forms of damage to lung parenchyma which remain clinically latent: (1) respiratory infections attenuated by modern chemotherapy and (2) inhalation of harmful air pollutants. The latter includes excessive smoking.

Treatment of Sciatica and Herniated Disk.—Since sciatica may be caused by a wide variety of conditions, its treatment varies greatly. The treatment of sciatic pain associated with arthritis of the spine or of the articular facets, osteoporosis of the spine, Pott's disease, spondylolisthesis, malformations of the vertebrae, spinal cord tumor, metastatic carcinoma, telangiectasis of the cord, sacroiliac arthritis and strain, and musculoligamentous conditions relating to the low back, to mention only a few conditions, all have their individual problems. There can be little disagreement that uniformity in treatment is not to be expected in such a variety of conditions. For the treatment of herniated disk, medical measures are sufficient in most circumstances. The majority of cases do not require operation. It is a mistake to regard medical treatment as merely preliminary to eventual operation. Medical treatment alone is sufficient in 75 to 83 per cent of cases. It consists of complete bed rest, analgesics, and physiotherapy including radiant heat and hot tub soaks. . . . . Medical treatment must always be preferred in sciatica due to herniated disk except in those cases of completely extruded disk which have failed to respond to medical treatment, in instances of frequent recurrence, and in those cases in which the individual choice is for surgical rather than medical relief. . . . The duration of medical treatment varies from two to eight weeks, depending on the severity of the sciatic pain, with most patients recovering within four weeks. This compares very favorably with the results of surgical treatment.—B. J. Alpers, M.D., Low Back Pain and Sciatica: The Case for Medical Management, *Medical Clinics of North America,* September, 1956.

TRIGEMINAL NEURALGIA

SPECIAL CONSIDERATIONS OF NONSURGICAL TREATMENT

Joseph G. Rushton, M.D.
and
Hugh N. A. MacDonald, M.D., Rochester, Minn.

Data regarding the effects of therapy in trigeminal neuralgia cannot be evaluated without knowledge of the spontaneous course of the disease. Analysis of 155 cases showed that 78 patients had experienced one or more spontaneous remissions lasting 6 months or longer and that 38 had had similar remissions of 12 or more months. This finding may have explained some reports of good therapeutic results from a variety of treatments, such as remissions lasting up to four years in 17 out of 39 patients after the extraction of apparently sound teeth. In patients who allowed many months to elapse before they sought treatment and who enjoyed long spontaneous remissions it could be assumed that the course of the disease would be somewhat benign. To tell whether a proposed treatment for trigeminal neuralgia is effective therefore requires a post-treatment observation period of at least six months and preferably a year.

It has long been recognized that the attacks of pain of trigeminal neuralgia may come and go for no apparent reason. "The duration of the attack is very indefinite, from one or two hours to several days, and its recurrence or exacerbation is alike in the day or night. . . . Equally uncertain is its period of return. As intimated, its revisitations are sometimes as regular as those of intermittents. But such instances are rare, and the interval may be a week, a month, a year or more. . . ."[1]

If a remission were to occur spontaneously at the time that some procedure was being carried out for the purpose of relieving the pain, the erroneous impression might be gained that the pain-relieving procedure was effective. A brief review of the history of various nonsurgical measures used in the past 100 years for the relief of pain of trigeminal neuralgia reveals that each agent has waxed and waned in favorable usage only to be replaced by a successor of equally dubious value. It is possible that the commonly occurring remission of pain has been an important factor in bringing about the premature conclusion that these remedies have been of significant benefit in the treatment of trigeminal neuralgia.

Inquiry into this matter has seemed worthwhile for the purposes of learning something of the natural history of trigeminal neuralgia, as it has been seen at the Mayo Clinic, and of discovering whether spontaneous remissions of pain are of such character as to create a problem in judging the effectiveness of a particular treatment for this condition. In an attempt to gain information along these lines we have studied the cases of 155 patients with trigeminal neuralgia seen at the clinic in 1953. We have not included the case of any patient with known intracranial tumor or aneurysm.

Review of Cases

The age of patients at onset of pain varied from 17 to 88 years. Although the disease is properly considered to be one of middle and later years of life, we found that 19 of the 155 patients, approximately an eighth of the total number, had noted onset prior to the age of 40 years. Seventy patients were men and 85 were women (table 1). Three patients had noted symptoms for 30 years or more, 10 for 20 to 29 years, 26 for 10 to 19 years, 40 for 5 to 9 years, 65 for 1 to 4 years, and 11 for less than 1 year. From these figures it cannot be assumed that spontaneous "cures" do not occur, but it seems reasonable to assume that such occurrences are rare.

TABLE 1.—*Age at Onset and Sex of 155 Patients with Trigeminal Neuralgia*

Patients, No.	Male, No.	Female, No.	Age at Onset, Yr.
1	..	1	17-19
5	3	2	20-29
13	4	9	30-39

By comprehensive medical care, I mean all those services by individual physicians and related professional workers, hospitals, nursing homes, and health departments that are required to extend the active life of older people. Obviously, no single individual or organization can provide all those services.

There is a growing awareness among the professions and the public that these services should be and can be planned, developed, and delivered by the community and its physicians—the state, the federal government, medical schools, and private organizations aiding and abetting the efforts of the community and the medical profession. The conviction that such community action is needed springs from the day-to-day experience of families, community agencies, and individual physicians in trying to obtain comprehensive care for the aged. And it springs from the nationwide experience of older people, their families, and taxpaying fellow citizens in trying to meet the costs of disabling illness.

Public Assistance

In a recent study of patients in nursing homes, the Public Health Service found that the average patient is 80 years of age and that more than half of the patients are supported by public assistance funds. Studies conducted by the Social Security Administration indicate that over 25% of persons accepted for public assistance give ill health as the cause of their dependency. Such findings emphasize the fact that old age for far too many of our people is almost synonymous with ill health and inadequate income. The economic burden of disability in older persons can be substantially lessened by comprehensive services for the aging in their own communities.

What can communities do in cooperation with their physicians to raise the health level of their older citizens and reduce the economic burdens of disability? In the first place, they must consider the totality of the problem, just as the physician must consider the whole individual in arriving at a diagnosis and instituting appropriate therapy. Since the health status of an older person is the sum of many factors, services must be planned to affect the whole—the physiological changes of aging and the psychological, social, and economic factors involved in producing the state of ill health or good health.

Planning for health of the aged, then, begins with a survey. Depending on the size and complexity of the problem, a survey can be made by teams ranging in size from a physician and a visiting nurse, supported by adequate biostatistical and clerical assistance, to the full complement of a community welfare council. In any case, the results will be far more satisfactory if the individuals involved represent the community at large and the various professions concerned in the physical, mental, and social well-being of the aged. The broader the representation on the survey team, the more comprehensive and—in the long run—the more effective will be the planning and the programs.

I want to emphasize strongly the need for active participation in any such surveys and programs by practicing physicians as individuals and as representatives of their medical societies. Indeed, there are too many instances in which needed services have not been developed because physicians have not been brought into the planning and program development at the earliest stages. It is all too common an error for community groups to plan health programs for physicians instead of with them, with the result that the key persons—the practicing physicians—in any program for care of the aging do not know what is expected of them, nor have they been consulted as to whether they can, professionally, deliver the services expected. The local health officer also is often neglected when a steering committee is organized. This too is unfortunate because the average health department does have skills and resources for organizing and developing community programs. It is a potential source of financial and professional assistance, both through its contacts with community institutions and through state and federal agencies.

In reverse, there have been equally short-sighted instances when public health and medical groups have attempted to develop community services without taking social welfare, industrial, and civic organizations in on the ground floor of their planning. The moral of these observations is that we are all in this together. We cannot carry out our responsibilities for the health of our patients or our communities without the help of other professional people and community leaders.

For example, one of the ideas now catching fire in a number of communities is the establishment of a "center" for the aging, where health counseling, group recreation, social casework service, nutritional advice, and referral to medically approved sources of care are provided. I have in mind the kind of place that older people can consider their own, a place where many of their needs can be met. A "center" of this type could eliminate the frequent referral of individuals from agency to agency with resulting confusion and frustration that often develops. Consolidated services for the aging could be operated by the local public welfare department or the health department, or both together. In communities with well-developed voluntary health and welfare services, it would be much more desirable for the united community services or the welfare council to operate such a center, with official and voluntary agencies jointly supplying whatever services or funds they can provide. As community organizations are now asking the public to subscribe to "united giving," so also the agencies could provide the greatest amounts of service to the most people at the least cost through a little "united giving" on their part.

Nursing and Restorative Care

Improvement of nursing home care is urgently needed in many communities. Training courses for the operators of nursing homes can be provided as part of a community's comprehensive program for health of the aged. Agencies responsible for the licensing and supervision of nursing homes and related facilities can provide many consultative services through local health departments. Public health nursing consultants, dietitians, sanitarians, and health educators all may have something to offer that will help the nursing home operators do the better job they would like to do in caring for their aged and infirm patients. The use of licensure to raise the standards of these homes is a practical point of departure, but results are more effective when it is not used as club but as an opening door to rendering services indirectly to the aging.

Home care programs, although varying widely in content and method of organization, offer excellent opportunities in the development of community services for the aging. Up to the present time, home care services have been provided chiefly for patients receiving public assistance or private welfare aid. If the values of auxiliary medical services in the home—nursing, physical therapy, and housekeeper services, to mention a few—are ever to reach the majority of disabled older people, they must be so organized and rendered as to attract the practicing physician and his patients.

No comprehensive health service for the aged will be complete without attention to restorative care. This begins with attention to the eyes, the ears, feet, and teeth—four organs that are neglected to an astonishing degree in older persons. Perhaps no single service can do more to reduce the amount of care that an elderly patient needs than provision of a hearing aid, a new pair of glasses, better dentures, or treatment of a painful bunion. An older person not otherwise handicapped can be transformed into a healthier, happier person by one or more of these simple aids. If he is otherwise handicapped, he will be able to function more freely and to cooperate more fully in efforts to treat the more serious handicap.

Of greatest importance in restorative care of the aged, however, is the goal each individual wishes to attain and will strive to attain. If health workers around our handicapped and bedridden older people continue to be satisfied just with keeping them alive and "comfortable," the accumulation of disability in the United States will never be reduced; instead, it will increase. If, however, we are determined to attain maximum restoration of function of which each patient is capable, we will reap a rich harvest of improved health and reduced costs of care.

Health workers in this field of restorative care are continually amazed at what "hopelessly" handicapped people can do if they are helped to help themselves. At one large city hospital (District of Columbia General Hospital), before active restorative services were begun, only 10% of the paraplegic patients were able to walk at the time of their discharge. Today, with vigorous restorative treatment, 90% of these patients leave the hospital walking and capable of complete self-care. And they stay in the hospital only half as long as patients with comparable handicaps stayed before restorative services were initiated. When we think what this means in terms of human values, to say nothing of savings in money, we are inclined to wonder why we have waited so long and why so few communities have taken up this challenge as well as others presented by the health problems of aging.

Summary and Conclusions

Planning health services for older people is part of the community's plan for health services to all individuals. It must take into account the totality of the older person's particular needs, especially with respect to prevention of chronic disease and restoration of the severely disabled. Preventive medicine has always been concerned with health promotion, aimed at improving the total well-being of the individual. Preventive medicine has been in the forefront of professional efforts to control disease.

Specialists in preventive medicine must give more leadership in their communities to the development of supplementary services. This will take time. Nevertheless, when we recall the successes achieved in the earlier efforts of public health workers and practicing physicians to control epidemics, we can anticipate similar benefits to the nation's welfare from joint action in health of the aging and chronic disease control.

Preventive medicine stands today at a critical point in its long and distinguished history. We have greater knowledge than ever before for the diagnosis, treatment, and prevention of disease. We have progressed far. But at this time, we need especially to think of medicine's role in our changing society and how we can shape that role for the greater good of society.

Changes come slowly—almost imperceptibly. They are not recognized by many of us until some critical questions arise affecting our particular sector in the medical world. Too often we have not had a part in helping to guide and direct these changes. If we are to have anything to say about them we must have ideas—imagination. We must do some thinking of our own as to what shall be preventive medicine's role in bringing to pass "complete physical, mental, and social well-being" as a standard of health in our country and throughout the world.

TREATMENT OF LOCAL ISCHEMIA DUE TO LEVARTERENOL (LEVOPHED) LEAKAGE WITH PIPEROXAN

Louis Pelner, M.D., Brooklyn, N. Y.

The vasodilating action of piperoxan hydrochloride has an important application in the treatment of the local ischemia that results when extravasations of levarterenol occur during intravenous injections. The ischemia is marked by coldness, pallor, and numbness and has sometimes gone on to necrosis. Three case histories are given to illustrate the prompt relief of the ischemia by piperoxan hydrochloride. The latter is injected subcutaneously in multiple punctures about the affected vein in the form of a solution containing 5 mg. in 20 cc. of sterile saline solution, and the amount needed varies from 20 to 30 cc. A satisfactory vasodilation occurs within one minute and is manifested by the return of a healthy pink color to the ischemic area.

Levarterenol (Levophed) bitartrate has deservedly become one of the mainstays in the treatment of the various types of shock due to surgery, trauma, overwhelming infections, drug reactions, and myocardial infarction.[1] However, one of the drawbacks has been the extreme care necessary to avoid infiltration which would often result in local ischemia and consequently necrosis of the skin. Even more baffling are the situations in which no infiltration has occurred, yet ischemia and subsequent necrosis of the skin has developed. Such incidents have limited the use of this lifesaving drug by many physicians. Recently two attempts have been made to counteract the local ischemia resulting from infiltration or extravasation of levarterenol solution by injecting phentolamine (Regitine) hydrochloride solution, either alone or with hyaluronidase.[2] The local use of hyaluronidase in this condition may possibly be harmful, as shown by case 1 presented below. In any case, it does not directly contribute to the satisfactory result.

Phentolamine was not immediately available when the patient described in case 2 below developed an ischemic area due to levarterenol infiltration, so piperoxan (Benodaine) hydrochloride was tried with immediate salutary effect.

Method of Use

A solution of piperoxan, 5 mg. in 2.5 cc. or ¼ of an ampul, was added to 17.5 cc. of sterile saline solution. The resulting dilution was 5 mg. in 20 cc. of solution. About 0.25 to 0.5 cc. of this solution was injected subcutaneously into the ischemic, cold area, first around the periphery and then within the area about 1 cm. apart. Within 30 to 50 seconds, each injected area developed a pink coloration and became warm to touch. More than 20 cc. may be used. Thirty cubic centimeters of this dilution was used in the patient in case 4 presented below, in which a very satisfactory result was obtained.

In the instance of case 3, a higher concentration of piperoxan was used (10 mg. in 5 cc.) added to 15 cc. of sterile saline solution for infiltration because of the large amount of levarterenol used in the infusion.

Case Reports

Case 1.—A 55-year-old woman was admitted to the hospital on March 23, 1957, with the complaint that 48 hours before she had developed a severe epigastric pain, which subsequently spread to both shoulders. Twelve hours before admission, the pain spread to both lower quadrants. The patient had a history of peptic ulcer years before, but she had had no pain of that type in the last few years. The patient was in shock and had a completely rigid abdomen.

A diagnosis of a perforated viscus with generalized peritonitis was made, and the patient was operated on promptly. At operation, approximately 8 qt. of a murky fluid was present in the peritoneal cavity. A perforated duodenal ulcer was found and was closed. Without warning, cardiac arrest occurred. The chest was entered, and cardiac massage was started. A levarterenol infusion (4 cc. levarterenol in 1,000 cc. glucose in saline solution) was given. A little difficulty was encountered in giving the intravenous injection because of the sudden drop in blood pressure. Infiltration of the levarterenol occurred, and the infusion was stopped. An area of ischemia about 12 cm. by 7 cm. was noted in the left antecubital fossa. Two cubic centimeters of hyaluronidase solution, 15 turbidity-reducing units (T. R. U.) per cubic centimeter, was infiltrated subcutaneously in the ischemic area. Within 15 minutes the ischemic area was at least twice the original size, and within two hours it was three times the size. Although the heart responded to cardiac massage initially, it again stopped three hours later. Cardiac massage was again instituted, and again the heart was revived. The patient died eight hours later. At the patient's death the ischemic area was three times the size it had been initially.

Case 2.—A 50-year-old man was admitted to the hospital on May 5, 1957, with a history that for the past three hours he had had severe constricting pain in the chest and left arm, associated with marked pallor and cold perspiration. He had had a severe coronary thrombosis a year and a half before. An electrocardiogram was consistent with a severe anterior wall infarction. He was given heparin sodium and bishydroxycoumarin (Dicumarol), with the amount rapidly increased until the required concentration was reached. Late in the day a few ventricular extrasystoles were noted and administration of quinidine was started. The next day

---

Attending Physician, Swedish Hospital.

the patient developed a few rales at both bases, and 2 cc. of mercaptomerin (Thiomerin) sodium was given. The same day, his blood pressure, which had been 120/80 mm. Hg, fell to 86/70 mm. Hg, so 2 cc. of mephentermine (Wyamine) sulfate (15 mg. per cubic centimeter) was given intramuscularly every hour.

The patient remained in critical condition. The next day he again developed precordial pain and a cold sweat, and the blood pressure was 60/40 mm. Hg and the pulse rate 30 per minute. A complete heart block had developed. A levarterenol infusion (4 cc. in 1,000 cc. glucose in water) was started, at 40 drops per minute. His blood pressure had risen slightly to 80/50 mm. Hg. On May 8, he was slightly better, when at 8:30 p. m. he suddenly complained that he did not have enough air and gave a loud outcry. The pulse was absent. Immediately artificial respiration was given, the levarterenol infusion was allowed to run in at a rapid rate, and atropine sulfate, 1/150 grain (0.00043 Gm.), was given into the infusion tubing. The patient's pulse and blood pressure responded in about five minutes. Ephedrine in oil, 1 cc., was given on the premise that this was a Stokes-Adams type of attack. The next day and the following day, the patient was much better, with the blood pressure remaining at 100/60 mm. Hg and the pulse about 65-70 per minute. The levarterenol infusion was continued at 30 drops per minute.

On May 10, I was called because of an infiltration due to the levarterenol solution. Actually there were two areas of infiltration, with a marked ischemic area in the left antecubital fossa measuring 13 by 8 cm., which had occurred six hours before, and a recent infiltration at the left wrist, which had occurred 15 minutes before. Each area was markedly blanched and cold and felt numb to the patient.

A solution of piperoxan (5 mg. in 2.5 cc.) was added to 17.5 cc. of sterile saline solution, and each area was infiltrated subcutaneously. The needle pricks were about 1 cm. apart, and about 0.25 to 0.5 cc. of the solution was injected in one place. Within 30 to 50 seconds each little injected area developed a pink color and the patient stated that the numbness was gone. The areas were inspected the next day and had a delicate pink coloration without evidence of ischemia. Because it was not known whether the solution of piperoxan would cause a drop in blood pressure, another infusion of levarterenol was started in the opposite antecubital fossa. However, this was discontinued when the blood pressure remained the same. The patient made an uneventful recovery and was discharged on June 11, 1957. The skin areas involved in the infiltration were entirely normal.

Case 3.—A 49-year-old male was admitted to the hospital on May 31, 1957, with a history that for the preceding three-month period he had had occasional precordial pain. On the day of admission the pain had been severe and continuous. He had a history of a previous attack of coronary thrombosis one year before, diabetes mellitus for 17 years, and blindness due to chronic glaucoma for one year.

On admission, the patient was pale and anxious, his pulse was thready, but his blood pressure was 115/80 mm. Hg. His electrocardiogram showed a depressed ST, and depressed ST wave in leads V_5, V_6, and CF_4. There was a deep QS wave in leads 2 and 3. He was given heparin and bishydroxycoumarin, but complained of almost continuous chest pain in spite of adequate doses of opiates.

On June 2 he complained of a sudden severe onset of chest pain, his blood pressure suddenly dropped to nothing, and the pulse became imperceptible. An infusion of levarterenol (8 cc. in 500 cc. glucose in water) was finally started in a leg vein after several attempts to find a suitable arm vein proved fruitless. The patient thrashed around in bed, and the levarterenol infusion infiltrated in an area measuring 15 cm. by 10 cm. This area became markedly blanched.

A solution of piperoxan was made up, with 10 mg. of piperoxan being used in 20 cc. of solution. The effect was exactly the same as that noted in case 2. Although the patient died three hours later from spreading of the initial infarction or sustaining of a fresh infarction, the ischemic area had remained pink.

Case 4.—A 42-year-old man was admitted on June 20, 1957, with a history of sudden onset of severe chest pain, dyspnea, and dizziness. He recalled two similar attacks, one year and six months previously. During those episodes, he had been hospitalized. He was a heavy drinker. Physical examination revealed a desperately ill patient. The pulse rate could not be counted. The heart rate was 180 beats per minute, with apparently regular rhythm. There were bilateral expiratory wheezes. The liver was enlarged four fingers below the costal arch, and there was slight edema of both legs. The blood pressure was 96/54 mm. Hg. The admission diagnosis was coronary thrombosis and possible cirrhosis of the liver. The electrocardiogram revealed ventricular tachycardia with a rate of 196 beats per minute. The patient had been given digitalis at the outset, which was stopped as soon as the electrocardiogram was read and quinidine substituted. The next day, the arrhythmia continued but the patient felt better.

That evening, the patient developed chest pain, associated with profuse perspiration, and developed shock. The blood pressure had dropped. Levarterenol, 4 cc. in 1,000 cc. glucose in water, was given at the rate of 30 drops per minute. The next day, June 22, the patient still had ventricular tachycardia, so that quinidine was given intramuscularly. The blood pressure was now 90/50 mm. Hg, and the levarterenol infusion was continued. On June 23, the tachycardia had stopped, and the patient suddenly uttered a cry and became temporarily unconscious. The heart rate was 32 beats per minute. The electrocardiogram showed complete heart block, idioventricular rhythm, and T wave inversions suggestive of coronary occlusion. Administration of levarterenol was continued. The patient's pulse was not of good quality.

That morning it was noted that the patient had a blanched area in the region of the needle puncture. The levarterenol solution was removed, and alcohol wet dressings were applied. About six hours later, when I inspected the area, it was noted that there was a 14 cm.-by-9 cm. area of induration which was blanched and cold and clearly demarcated from the rest of the skin. Although the solution had not actually infiltrated, it had extravasated through the needle puncture into the surrounding skin.

A solution of piperoxan in saline solution made up exactly as noted in case 2 was infiltrated subcutaneously throughout the ischemic area. An immediate pink coloration to the skin was noted, and the area became warm. Thirty cubic centimeters of the prepared solution was used. After the infiltration with piperoxan, it was noted that no drop in blood pressure had resulted. The area was inspected daily and appeared entirely normal.

The patient has been improving satisfactorily. At the time this paper was written the electrocardiogram showed regular sinus rhythm with first degree heart block; the blood pressure was 100/60 mm. Hg, and the pulse rate was 76 per minute.

Prevention and Reversal of Ischemia

In the latest literature on levarterenol, the manufacturer [3] lists the following precautions: 1. Do not leave patient unattended. 2. Antecubital vein of arm is preferred for infusion site. 3. Avoid hand veins. In elderly patients or in those with peripheral occlusive vascular disease avoid leg veins whenever possible. 4. Avoid leakage about needle. Extravasation may cause local ischemia and sloughing.

In spite of all necessary care and observation, extravasation of the solution may still occur, even though the needle is firmly in the vein and has not been dislodged by the patient.[4]

Shapiro and Perlow [4r] reported six cases of skin necrosis after intravenous administration of levarterenol. They state that the number of instances of severe local ischemia and transient phlebitis not associated with skin necrosis is not known but is undoubtedly much more frequent than actual necrosis. According to them, local infiltration and stagnation of the levarterenol in the vein may result in skin necrosis. In the latter instance, diffusion of the solution through the wall of the vein would offer an explanation for involvement of the tissue along the course of the vein.

Obviously some method of prevention of the ischemia and its reversal if already present is mandatory, if this remarkable drug is to remain in use. Shapiro and Perlow [4r] did some experimental work in dogs to answer some of these questions. Their work indicates that perfusion of the levarterenol solution through an undamaged vein wall is conceivable under conditions of sluggish circulation and stagnation of the blood within the veins. These conditions are found in the shock-like states which are precisely the emergencies for which levarterenol is used. An acute spasm of the vein, which so commonly occurs after the first influx of the levarterenol solution, may intensify the stagnation of blood. An injection of a solution without levarterenol will easily overcome such an obstruction. Therefore, Shapiro and Perlow recommended that in clinical use a solution without levarterenol should be used until a satisfactory flow has been reached, after which transfer to the pressor solution can be made. Further, if the clinician is unaware of the possibility of an acute venospasm, he may manipulate the needle which may increase the likelihood of perivascular infiltration of the pressor solution.

Shapiro and Perlow further recommend the insertion of a cannula or fine polyethylene tube high into the vein where the flow is more rapid than in the peripheral vessel and where the solution is quickly diluted by the large volume of blood. In addition, they make the point that the extremity should be elevated to aid in the venous return which would also prevent ischemia of the skin due to stasis of the solution in the vein. They further state that if the levarterenol solution is required only intermittently, it is advisable to flush out the vein with saline solution by means of a three-way stopcock in order to prevent stagnation of the pressor solution in the vein.

The points made by Shapiro and Perlow are interesting and useful but not widely applicable because of the training and the additional equipment necessary. Furthermore, it seems that extravasation of the levarterenol solution does not usually occur at the start of the infusion, but only after it has been running for several days. Thus other factors besides the initial acute venous spasm must be involved.

Hardie and Hunter [5] state that arteriosclerosis obliterans, thromboangiitis obliterans, and Raynaud's disease preclude the use of levarterenol infusions. They state that when long-term administration is necessary, the drug should be given above the antecubital or popliteal fossa in a vein of adequate diameter and blood flow. A polyethylene catheter threaded centrally through a large intravenous needle increases the amount of blood flow, in their view. They state that the nourishment of the vein wall should be maintained by administration of oxygenated whole blood with the pressor agent or intermittently by a "Y" connection. Also they state that vasoconstriction can be relaxed by stopping the administration of the drug and giving oxygenated whole blood and by injecting hyaluronidase and 1 to 2% procaine.

I feel, on the basis of case 1, that hyaluronidase may cause the ischemia to spread before the vasodilator becomes effective. Hardie and Hunter [5] recommend that heat not be used, because it increases the metabolic demands of the ischemic tissue. Years ago, I [6] showed in an experimental study that procaine will partially antagonize the vasoconstrictor effects of epinephrine, but it is doubtful if it can reverse the effects of levarterenol.

One need not go into great detail about the remarkable utility of levarterenol. It may be summed up in the quotation: "Levarterenol (Levophed) has proved to be the potent and effective vasopressor for the treatment of hypotension and shock following acute myocardial infarction. In the great majority of instances the blood pressure rises promptly after the institution of this therapy." [1a] Jamison and co-workers [7] believe that the beneficial effects of levarterenol are due to an increase in coronary blood flow, which is much greater proportionately than the rise in blood pressure. They claim that the oxygen supply of the heart muscle is increased to a greater extent than the oxygen utilization.

Sampson and Griffith [1c] state that levarterenol administered by intravenous drip is the most effective therapy now available in combating severe hypotension and is useful in overcoming shock due to acute myocardial infarction, cerebral arterial occlusion, pulmonary infarction or embolism, or shock associated with surgical, postsurgical, or traumatic complications. In a footnote to their article, the authors made the significant observation that when used alone levarterenol often results in thrombosis and necrosis of the vein employed, at or near the site of injection, especially so if the drug escapes into the surrounding tissues. They found, however, if 10 mg. of heparin is added to each 500 cc. of 5% glucose solution to which 8, 12, or even 16 mg. of levarterenol has been added, it will prevent thrombosis or necrosis of the veins. They state that even if a small amount of the solution should escape into the tissue the resulting inflammatory reaction does not progress to necrosis. If these findings can be duplicated, then the problem of administration of levarterenol is indeed solved. However, many of the patients given levarterenol have been given heparin and bishydroxycoumarin, and extravasation of a solution of levarterenol still caused ischemia and subsequent necrosis in some instances. Perhaps the concentration of heparin actually given in the levarterenol solution is greater than would be the concentration of heparin in the ischemic area when heparin is given intramuscularly. Nevertheless the method of administration of Sampson and Griffith is certainly worth a trial.

Treatment of Ischemic Area

The methods of treatment used for the ischemic area after levarterenol infiltration or extravasation have until recently proved largely unsuccessful. Injections of hyaluronidase and procaine[5] in the ischemic area did not prevent necrosis. Nourishment of the vein wall by transfusions of oxygenated whole blood has not changed the picture.[5] Recently two articles have appeared describing a treatment that has proved successful.

McGinn and co-workers[2a] used infiltration of phentolamine (Regitine) hydrochloride and hyaluronidase and Zucker[2b] used phentolamine alone into the ischemic area caused by levarterenol infiltration. Phentolamine is a physiological antagonist to levarterenol and is used in the diagnosis of pheochromocytoma, a tumor of the adrenal medulla, which produces levarterenol. Both of these articles describe the use of 5 mg. of phentolamine in 20 cc. of water, in one case with a solution of hyaluronidase and in the other without, as an injection into the ischemic area. Based on the results of my first case in this report (case 1), I should be hesitant to use hyaluronidase, since it will cause not only a diffusion of phentolamine but a widespread diffusion of the levarterenol as well. In any event, multiple infiltrations of a solution of phentolamine alone work just as well. According to the two articles, injections of phentolamine result in a "pinking out" of the ischemic area in from five to seven minutes.

At the time of my first treated case (case 2), phentolamine was not available to us at the hospital. We did have piperoxan (Benodaine) hydrochloride, and since this drug is also a physiological antagonist to levarterenol,[8] we used this in the dosage of 5 mg. in 20 cc. of sterile saline solution by multiple subcutaneous infiltration. A pink coloration developed in the ischemic area almost at once (30 to 50 seconds), and the area recovered completely in each case. Because of the massive dose of levarterenol used in case 3, 10 mg. of piperoxan in 20 cc. of solution was used as the infiltrating agent. Whether 5 mg. in 20 cc. would have been enough is not known.

In case 2, we were afraid to use the piperoxan solution to infiltrate the ischemic area before starting another infusion of levarterenol in the opposite arm. This precaution proved not to be necessary in this or in the other cases, because piperoxan has no effect on normally mediated blood pressure but has an effect only on blood pressure elevation associated with levarterenol secretion, as in pheochromocytoma.

Summary

Three patients with marked ischemia of the skin as the result of infiltration or extravasation of a solution of levarterenol (Levophed) bitartrate were treated with infiltration of a solution of piperoxan (Benodaine) hydrochloride. A satisfactory reversal of the ischemia resulted in each of the cases in which it was tried.

Dr. Emanuel Schwartz, Attending Physician at the Swedish Hospital, Brooklyn, N. Y., gave permission to report case 4, in which treatment was under his direction.

ROUTINE MEASUREMENT OF RESPIRATORY RATE

AN EXPENSIVE TRIBUTE TO TRADITION

Ross C. Kory, M.D., Wood, Wis.

The routine repeated measurement of the respiratory rate is of clinical value in less than 5% of patients in a hospital, and furthermore physicians themselves rarely show an interest in such measurements. As a result of such indifference, nurses have been increasingly casual in their measurement of respiratory rates, and, in many cases, though a figure is recorded, no actual measurement was made. In one carefully controlled experiment measurements of respiratory rate were carried out in 58 patients within minutes of the routine ward measurements. The ward records showed 57 of these patients as having a rate between 18 and 22 per minute; 40 having a rate of exactly 20. The real range was from 11 to 33 per minute, only five patients showing a rate of 20. If recording the respiratory rate is important, the character of the breathing is of equal importance. Nursing personnel should recognize abnormal breathing patterns and bring these abnormal findings to the attention of the physician. It is suggested that routine recording of respiratory rates be limited to those cases or on those hospital wards where the physician specifically orders such measurements. This not only would improve the accuracy of the measurements and clinical records but also would save millions of hours of personnel time each year.

The measurement of the respiratory rate in hospital patients has been a routine procedure for many years. At the turn of the century a large number of hospital patients were admitted for acute infectious diseases, such as typhoid, malaria, and bacterial pneumonias. Since precise diagnostic procedures were not available and since therapy for most of these diseases was nonspecific and "expectant," serial observations of the "vital signs" were of great clinical importance. Under such conditions, frequent measurements of the respiratory rate served as a valuable prognostic aid.

As medical knowledge has increased, however, with improved methods of diagnosis and treatment, the routine repeated measurement of the respiratory rate is of clinical value in only a small percentage of hospital cases. Nevertheless, the tradition has been firmly established, and hospital patients continue to have their respiratory rate recorded, as a matter of routine, along with the body temperature and pulse rate. Since this measurement has not been of particular inconvenience to physicians, the tradition has been permitted to continue unchallenged even though the physicians themselves rarely show interest in such measurements. As a result of this indifference, the nurses have been increasingly casual in their measurement of respiratory rates, so that, in many cases, a routine figure is recorded, no actual measurement having been made.

It is the purpose of this study (1) to reexamine the clinical value of the routine measurement of the respiratory rate, (2) to assess the accuracy of such measurements in representative hospitals, and (3) to point out the approximate annual cost of personnel time used in this routine procedure in our hospitals.

Respiratory rates can be abnormal in only two ways—an increased respiratory rate (tachypnea) or a decreased respiratory rate (bradypnea). The chief conditions in which the respiratory rate increases are pneumonia, pleurisy, other painful conditions of the chest wall, any condition which obstructs the air passages, fever, anemia, congestive heart failure, metabolic abnormalities, neurogenic and psychogenic defects, limitation of the depth of inspiration as in peritonitis or increased intra-abdominal tension, and conditions which increase the carbon dioxide tension of the blood.[1] In none of these is tachypnea per se either diagnostic or of great help in management, although observation of the character of the respiration is sometimes helpful. It should be noted that "an increased [*respiratory*] rate is often observed in the normal person because of embarrassment or the emotional distress occasioned by the examination." [1A]

A decreased respiratory rate is seen in such con tions as lowered metabolism, drug narcosis, sho and head trauma in which there is a marked incre in intracranial pressure.[1A] In the latter three conditi the respiratory rate may be quite important, but equal importance is the character of the breathing. is particularly important that nursing personi recognize at an early stage such abnormal breathi patterns as dyspnea, stridulous breathing, the de sighs of emotional tension, Kussmaul's respiratio and respiration of either the Cheyne-Stokes or B type and that such abnormal breathing be broug to the attention of the physician.

Clinical Usefulness of Routine Measurements

In order to evaluate the clinical usefulness routine measurements of respiratory rate, two a proaches were used (table 1). A survey of 200 r selected consecutive clinical records at the Vetera Administration Hospital, Nashville, Tenn., was carri out in which each record was carefully reviewed a

---

From the Investigative Medicine Service, Veterans Administration Hospital, Wood, Wis., and the Department of Medicine, Marquette University School of Medicine, Milwaukee.

day by day condition of the patient evaluated as whether measurements of the breathing rate would of any value. This evaluation was conservative, luding, for example, a blanket assumption that piratory rate measurements would be of value for eral days after each operative procedure, however jor. Even with this conservative approach, the vey revealed that in a total of 5,006 patient days, re were only 238 days (4.7%) in which measurents of the respiratory rate were of any clinical value. imilar survey of 100 consecutive unselected clinical ords at the Veterans Administration Hospital, ood, Wis., suggested that respiratory rate measurents were needed in only 204 (3.3%) of 6,169 total tient days.

The second approach was carried out by means of ect questioning of the 40 physicians directly reonsible for the care of 1,067 patients in the Veterans dministration Hospital, Wood, Wis. These patients re distributed as follows: medical, 378; surgical, 2; tubercular, 160; and neuropsychiatric, 207. Each ysician was asked how many of the patients directly der his care would need to have measurements of spiratory rate taken in the event that routine measureents were eliminated. Each doctor was urged to inude any patient in whose respiratory rate he was terested for any reason whatsoever. Even with this rging, there were only 49, or 4.6%, of a total of 1,067 ospital patients for whom the patient's physician onsidered repeated respiratory rate measurements of ny clinical importance (table 1).

These studies, although carried out independently, how remarkable agreement and strongly suggest that, a general medical and surgical hospital, measureents of respiratory rate are of clinical usefulness in ss than 5% of the patient days.

Accuracy of Routine Measurements

The lack of medical interest in respiratory rates has esulted in apathy on the part of nurses toward this easurement. In many hospitals "respirations" are easured in a perfunctory manner and are likely to e highly inaccurate. These inaccuracies were reeatedly demonstrated by comparison of measurements of respiratory rates taken in studies on patients n a cardiopulmonary laboratory with those measurements routinely recorded in the clinical record of the same patient on the same day (fig. 1). The routine measurements of rates recorded on the ward records were between 18 and 22 per minute in 49 of the 51 patients studied, and 34 of the rates were charted at exactly 20 per minute. In contrast, the respiratory rates carefully measured in the cardiopulmonary laboratory on the same patients on the same day ranged from 10 to 35 per minute. Figure 1 illustrates the absence of correlation between these sets of measurements.

In order to duplicate the conditions as nearly as possible, careful measurements of respiratory rates were carried out at intervals during one day on all patients on one acute medical and one acute surgical ward. Our measurements were made either a few minutes before or a few minutes after the routine temperature, pulse, and respiration measurements (fig. 2). In this entirely separate group of patients, the routinely recorded ward respiratory rates were between 18 and 22 per minute in 57 of 58 patients, 40 of these being recorded as exactly 20 per minute. In this group, our carefully measured rates ranged from 11 to 33 per minute with no correlation between the two sets of measurements. It should be further noted that two patients were found by us to exhibit typical

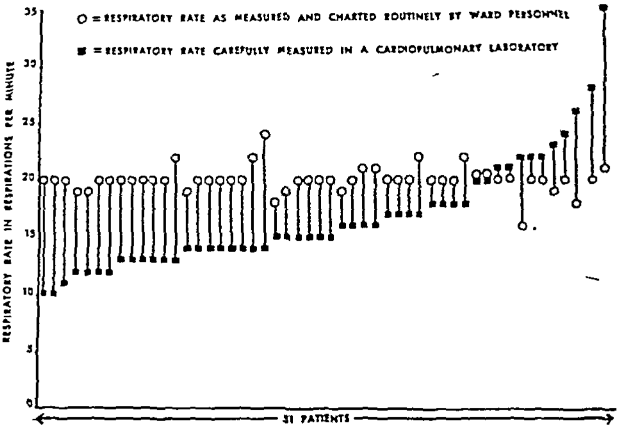

Fig. 1.—Comparison of respiratory rates measured in cardiopulmonary laboratory with routinely recorded ward "respirations" for same patients on same day.

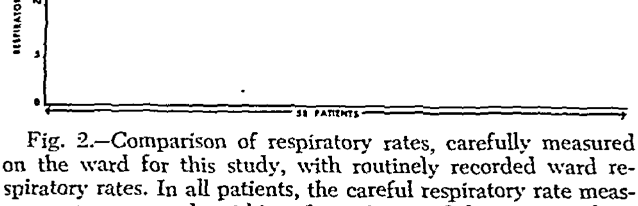

Fig. 2.—Comparison of respiratory rates, carefully measured on the ward for this study, with routinely recorded ward respiratory rates. In all patients, the careful respiratory rate measurements were made within a few minutes of the routine taking of "temperature, pulse, and respiration" by ward personnel.

Cheyne-Stokes respiration. No notation of this fact was found in either patient's clinical record, although the respirations were charted faithfully at 20 per minute on both patients.

The data obtained in these two studies strongly suggest that the routine respiratory rates recorded on the wards are much more likely to be 20±2 per minute than to represent the correct respiratory rate. In order to test this thesis, the clinical records of 148 patients at Veterans Administration Hospital, Nashville, Tenn., and 100 patients at Veterans Administration Hospital, Wood, Wis., were checked for the total number of respiratory rates measured in the patient and for the number of these rates which fell between 18 and 22 per minute (table 2). Of the 6,953 recorded respiratory rates in 148 patients at Thayer Veterans Administration Hospital in Nashville, 6,532, or 94%, ranged between 18 and 22 per minute. Of 6,757 respiratory rate measurements in 100 patients at Veterans Administration Hospital, Wood, Wis., 6,363, or 94%, were within the 18 to 22 range. The fact that only 6% of 13,000 respiratory rates as recorded were outside of the 18 to 22 range is further evidence that the recorded measurements are unreliable, particularly since the normal range for males is more nearly 14 to 18 per minute than 18 to 22.[2]

TABLE 2.—*Evaluation of Accuracy of Routine Respiratory Rate Measurements*

Type of Study	Hospital Where Study Was Conducted	No. of Patients	Total No. of Respiratory Rates Measured	No. of Recorded Respiratory Rates Between 18 and 22 per Min.

Yearly Cost of Personnel Time Used in Unnecessary Measurements

The average daily patient population (excluding neuropsychiatric patients) in United States hospitals is in excess of 650,000. If 5% of these (32,500) are assumed to need respiratory rate measurements, over 600,000 patients would appear to be receiving unnecessary routine respiratory rate measurements each day. If we make the conservative assumptions (1) that the 600,000 patients will receive an average of only one measurement a day and (2) that this measurement, together with the charting, will require only one minute's time, it still follows that 600,000 minutes of personnel time is devoted each day to this needless measurement. These daily 600,000 minutes represent 3,650,000 hours per year of wasted time of nurses and nursing assistants, both of whom are in extremely short supply in our hospitals. If a further conservative assumption is made that the average salary of such personnel is $1.50 per hour, the monetary expression of this annual wasted time is over $5,500,000.

Comment

Our data have indicated that measurement of respiratory rate serves a useful purpose in less than 5% of patient days and that the routinely recorded respiratory rates are highly inaccurate. Both of these statements have long been recognized by many physicians, but no systematic effort has previously been made to analyze this problem.

The repeated appearance in patients' hospital records of such inaccurate and unreliable data can never be defended as "good medical practice." The complete omission of such data would appear to represent better medical practice than does perpetuation of these erroneous records. It should be emphasized that respiratory rate measurements may be important in certain types of patients. In these as well as other patients the observation of the character of the breathing is at least as important as measurement of the rate.

It is proposed, therefore, that measurement of respiratory rate be continued in those cases or on those wards where the physician specifically orders that such measurements be made but that measurement of respiratory rate be eliminated as a "pan-hospital" routine. It is further proposed that the character of the patient's breathing be observed and recorded along with an accurate measurement of respiratory rate in those patients who need such measurements.

Summary and Conclusions

The data herein presented demonstrate that each year over 3,500,000 hours of personnel time (representing over $5,500,000) are devoted to an unreliable largely useless routine which has been continued in hospital procedure wholly because of tradition. The thesis espoused in this report is that the elimination of these routine measurements would in itself improve medical practice and patient care, by eliminating erroneous information from patients' hospital records and by freeing nursing personnel for more important duties. In place of this routine, the physician would specify those patients or particular wards in which he considered close observation of respiration necessary. The nurse, in turn, would observe the character as well as the rate of the "respirations" in such patients. Such a proposal should result in improved patient care and more accurate medical records and at the same time save over 3,500,000 hours of personnel time each year in United States hospitals.

CLINICAL NOTES

TERMINAL BLOOD ALCOHOL CONCENTRATIONS IN NINETY-FOUR FATAL CASES OF ACUTE ALCOHOLISM

Sidney Kaye, Ph.D.
and
Harvey B. Haag, M.D., Richmond, Va.

The observations reported herein were made for the urpose of obtaining additional data on (*a*) the erminal blood alcohol levels of persons dying from ncomplicated acute alcoholic poisoning and (*b*) the nterval of time between discovery of the patient in a omatose state (or time of last known alcohol ingeson) and death. From these combined data, an estimate, based on the rate of alcohol elimination, can hen be made as to the probable magnitude of the ntemortem blood alcohol concentrations. Such nowledge may influence the prognosis in cases of lcoholic intoxication and, from the medicolegal point f view, assist in more accurately establishing death s being due to acute alcoholic intoxication. Pertinent nformation and discussion on these matters is limited argely to publications of Jetter[1] and Jetter and McLean.[2]

During the period 1948-1955, we have had opporunity to study 94 cases in which the histories, medical xaminers' reports, gross and microscopic postmortem indings, and chemical analyses ruled out other ecognizable common causes of death except acute lcoholism. The majority of these victims were males between 25 and 50 years of age who were alcohol habitués and who had died a number of hours after appearance of coma or last known ingestion of alcohol. All the deaths occurred in Virginia. Blood for alcohol level determinations was drawn from the heart within eight hours after death. Alcohol concentrations were determined by a modification of the Nicloux method.[3] The interval between time of coma (or last alcohol ingestion) and death was obtained from the medical examiners' reports; understandably many of these figures represent, by and large, approximations, in view of which only the range of figures is given. The results are tabulated in the table.

Study of the table reveals, first, that in this group terminal blood alcohol values ranged from 180 to 600 mg. per 100 ml. of blood and, second, that the blood alcohol concentration at death was found to be inversely related to length of survival. One of us[4] found, from a study of nine human volunteers, that the blood alcohol level decreased at an hourly rate of 22±5 mg. per 100 ml. of blood; this is in keeping with the figures given by Harger and Hulpieu[5] and Jetter.[1] Hence, assuming that the blood alcohol concentration falls at a rate of approximately 20 mg. per 100 ml. of blood per hour, then, from the known duration of survival after coma and the terminal blood alcohol values, one can calculate the probable antemortem blood alcohol level at about the time the patient was first seen in coma (or known to have had his last drink). When this computation is made with the various time intervals and terminal blood alcohol values noted in our cases, calculated average antecedent values agree very well, i. e., about 500 mg. per 100 ml. of blood for those dying in 10 to 16 hours, to 600 mg. per 100 ml. for those dying within 1 to 2 hours. This does not mean necessarily that higher values may not have existed.

These findings are in keeping with observations and opinions reported by others.[6] Jetter,[1] for instance, cites one case in which the patient died about three hours after drinking two to three pints of whisky; the terminal blood value was 720 mg. of alcohol per 100 ml. of blood. In a second case, the patient died 18 hours after onset of coma; the postmortem blood alcohol concentration was 40 mg. per 100 ml. Hence it would appear that death need not (and probably seldom does) ensue at the height of the blood alcohol concentration but can follow hours later (due probably to irreversible and progressive central nervous system injury initiated at the time of the high level of alcohol). During this interval, considerable amounts of alcohol are metabolized and excreted, the blood alcohol concentration thus being lowered to that which is found on postmortem examination. These observations are substantiated by results obtained with animals,[7] in which it was noted that death almost never occurred at the peak blood alcohol level after oral alcohol administration with just fatal doses. In all probability, a similar situation exists with respect to other central nervous system depressants, notably the barbiturates.

Terminal Blood Alcohol Concentrations in Ninety-four Patients with Acute Alcoholism

Alcohol Values, Mg./100 Ml.			
Range	Median*	Patients, No.	Time Interval† to Death, Hr.
180-250	220±30	4	10-16
250-300	280±15	15	8-12
300-350	330±14	18	6-10
350-400	390±16	13	6-10
400-450	430±12	14	3-8
450-500	470±14	15	3-8
500-550	530±14	7	1-4
550-600	580±15	8	1-2

* Median for 94 patients = 400±100 mg. alcohol per 100 ml. of blood.

† Time interval between discovery of patient in comatose state (or time of last alcohol ingestion) and death.

From the departments of legal medicine and pharmacology, Medical College of Virginia and Office of the Chief Medical Examiner, State of Virginia.

Jetter[1] further states that in about 2,000 cases in which antemortem blood alcohol level estimations were done, he had never seen survival when the antemortem blood alcohol value was above 500 mg. per 100 ml. blood. In only three of his cases were postmortem blood alcohol values 500 mg. per 100 ml. or above. In over 4,000 examinations that we have made during the past eight years, we have never encountered a postmortem alcohol value in excess of 650 mg. per 100 ml. of blood.

Summary and Conclusions

Ninety-four patients with uncomplicated fatal acute alcoholism were found to have terminal blood alcohol concentrations ranging from 180 to 600 mg. per 100 ml. of blood. These values varied inversely with the length of time of survival after discovery of the patient in coma (or after the last drink); that is, the longer the period of survival, the lower the terminal blood alcohol value. Calculated antemortem concentrations at some previous time varied between 500 and 600 mg. of alcohol per 100 ml. of blood. From this, and in keeping with the findings of others, it appears that patients with levels of alcohol of about 500 mg. per 100 ml. of blood and above are foredoomed, in the absence of effective therapy, although at death the blood alcohol value may be only a fraction of this figure.

A SIMPLE, INEXPENSIVE COLOSTOMY APPLIANCE

Sidney Hirsch, M.D., Cedarhurst, N. Y.

A simple, inexpensive colostomy appliance can be made by using common 40-gauge clear plastic, from which the rear window of a convertible car is usually made. This material is soft and pliable and molds itself nicely to the abdominal contour. It is easily cut so that its central opening can be made quite large to allow its use shortly after the performance of the colostomy when the external portion of the intestine is still quite large because of the edema.

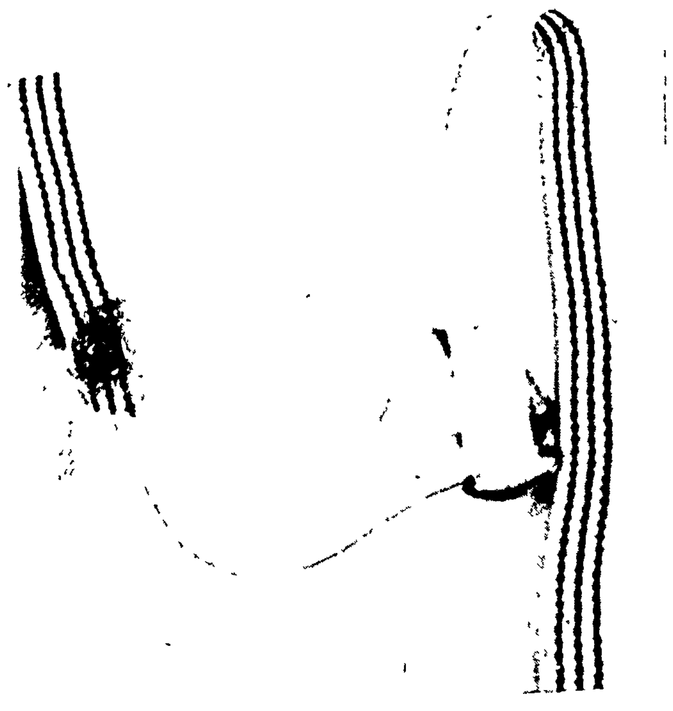

Fig. 1.—Disk of 40-gauge clear plastic, with Dot Snapper fastener at either end.

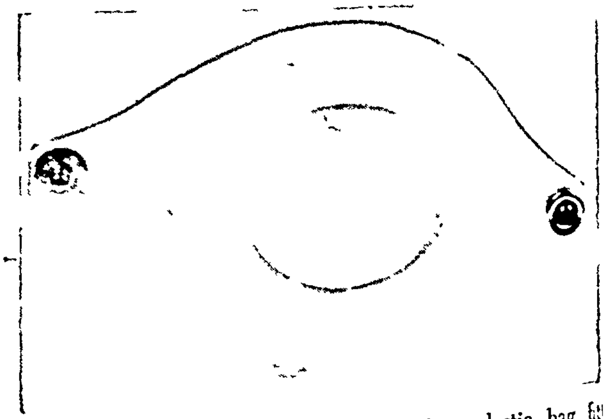

Fig. 2.—Colostomy appliance, showing plastic bag fitting through center opening of disk and webbed elastic strap fastened at each end.

The clear plastic is cut from a sheet in the design shown in figure 1. At either end is a Dot Snapper fastener. To one end the webbed, elastic strap is fastened and to the other end the Dot buckle. The usual plastic bag fits through the central opening and its ends turn over the circular portion of the plastic disk (fig. 2).

GRADUATE MEDICAL EDUCATION IN THE UNITED STATES

ANNUAL REPORT AND DIRECTORY OF APPROVED INTERNSHIPS AND RESIDENCIES, AND RÉSUMÉ OF THE REQUIREMENTS OF EXAMINING BOARDS IN THE MEDICAL SPECIALTIES PREPARED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Arthur N. Springall, M.D., John Hinman, M.D., and Willard V. Thompson, M.D.

ANNUAL REPORT

The 31st Annual Report on Internships and Residencies consists of detailed information and statistical data on all intern and resident training programs approved by the Council. Approval is limited to programs in hospitals located in the continental United States, the Canal Zone, Hawaii, and Puerto Rico. The report is composed of statistical tables on internships and residencies with detailed explanations and interpretations; a statement regarding the National Intern Matching Program; a brief description of the Internship Review Committee and the various residency review committees and their activities; a brief paragraph on foreign medical graduates; a statement of policy regarding straight internships; and a résumé.

The Directory of Approved Internships and Residencies is published immediately following the report. The hospitals which offer approved intern training programs are listed according to geographical location. Information given consists of the hospital control, number of hospital beds, number of annual admissions, autopsy rate, length of internship, stipend, and number and types of internships offered. Hospitals are also listed according to types of internships offered. A list of internships in Canada approved by the Canadian Medical Association is included.

The residency section lists the hospitals approved for residency training according to specialties. In addition to the statistical data presented, the names of the chiefs of services are listed, and additional information is included similar to that given in the internship section. A subsequent listing by state and city indicates the specialties for which each hospital is approved.

The entire report is based on detailed information furnished by each hospital approved for intern and/or resident training. The statistical data in the tables represent the intern and resident situations as of Sept. 1, 1956. These figures, therefore, may be in some instances at variance with those presented in the Directory of Approved Internships and Residencies, as the latter refer to appointments beginning July 1, 1958.

The Council acknowledges with gratitude the cooperation and assistance of the medical staffs and the administrators of hospitals listed. The publication of this report was made possible by their furnishing the statistical data requested. The following organizations collaborated with the Council in approving residency programs:

Advisory Board for Medical Specialties
American Academy of General Practice
American Board of Anesthesiology
American Board of Dermatology
American Board of Internal Medicine
  Subspecialty Board on Allergy
  Subspecialty Board on Cardiovascular Disease
  Subspecialty Board on Gastroenterology
  Subspecialty Board on Pulmonary Diseases
American Board of Neurological Surgery
American Board of Obstetrics and Gynecology
American Board of Ophthalmology
American Board of Orthopedic Surgery
American Board of Otolaryngology
American Board of Pathology
American Board of Pediatrics
  Subspecialty Board on Allergy
American Board of Physical Medicine and Rehabilitation
American Board of Plastic Surgery
American Board of Preventive Medicine
American Board of Proctology
American Board of Psychiatry and Neurology
American Board of Radiology
American Board of Surgery
American Board of Urology
Board of Thoracic Surgery
American College of Physicians
American College of Surgeons

The Annual Report and the lists of approved internships and residencies are reprinted as the Directory of Approved Internships and Residencies. Copies of this reprint will be furnished upon request to the Council.

The Annual Report furnishes information on graduate medical education (internships and residencies) to those interested, including medical students, hospital administrators, medical educators, and other individuals and organizations. The primary purpose of the report is to provide necessary information to young physicians beginning their professional careers who desire to undertake further medical education and training.

INTERNSHIPS

In table 1 there are listed the number of hospitals offering approved internships and the number of internships offered for the past 10-year period. For the intern year beginning July 1, 1956, 852 hospitals offered a total of 11,895 intern positions. These figures represent a decrease of 15 (2%) in the number of hospitals and an increase of 279 (2%) in the number of positions over the preceding year. This number of internships available is the largest number ever offered.

Miss Mary A. McGovern and Mrs. Helen Neitzel were responsible for much of the detail work in the preparation of the lists of approved internships and residencies, and the staff of the Machine Records System was responsible for the IBM statistical tabulations.

Represented in these figures are the approved internships in hospitals in the continental United States and in its territories and possessions, including one hospital in the Canal Zone, four in Hawaii, and eight in Puerto Rico.

The disparity between the number of American medical school graduates and the number of internships available is increasing. In 1956, there were 6,845 graduates of approved American medical schools. Therefore, there were approximately 5,000 positions available during the year 1956-1957 which could not be filled by American graduates. An estimated 2,500 of this number were filled by graduates of foreign medical schools. During the past 10 years, the number of hospitals offering approved intern training programs has increased about 6%, while the number of internships offered has increased 31%. During the same period, the number of interns per hospital has increased from 11.3 to 13.9.

Table 1.—*Approved Hospitals and Internships, 1948-1957*

Year of Publication	No. of Hospitals	No. of Internships
1948	807	9,118
1949	807	9,124
1950	794	9,398
1951	828	10,044
1952	865	11,467
1953	856	11,006
1954	844	10,624
1955	850	11,048
1956	867	11,616
1957	852	11,895

Internships, by Type of Service

A breakdown of approved internships according to type of service is given in table 2. Rotating general and rotating with emphasis on a particular service are included in the category of rotating services. Straight internships include straight service assignments to medicine, surgery, pediatrics, pathology, and obstetrics-gynecology. Mixed internships include those where assignments are made to two or three of the four major services (medicine, surgery, obstetrics, and pediatrics).

Table 2.—*Number of Internships, by Type of Service, 1956-1957*

Type of Internship	No. of Approved Programs	No. of Internships: Filled Sept. 1, 1956	Vacant Sept. 1, 1956	Percentage Filled
Rotating general	809	8,593	1,786	83
Other rotating	31	68	9	88
Totals	840	8,661	1,795	83

---

* Number of intern training programs in 852 approved hospitals.

For the intern year beginning July 1, 1956, 852 hospitals offered 1,101 approved intern training programs involving 11,895 intern positions. While the number of internships has increased slightly during the past year, the relative percentage of the three types of internship remains approximately the same. Table 3 represents these percentages for the types of internships for the past five years. Variation during this period has been slight.

On Sept. 1, 1956, 83% of the rotating internships were filled. Mixed internship occupancy increased from 84% in 1955 to 91% in 1956. There was also a slight increase in the occupancy of the straight internships from 83 to 85%. The over-all occupancy rate for internships on Sept. 1, 1956—83%—was the same as for 1955.

	100.0%	100.0%	100.0%	100.0%	100.0%

Internships, by Type of Hospital Control

The distribution of internships by type of hospital control is shown in table 4. Forty-two federal hospitals offered 643 positions, or 5.4% of the total number of internships. Intern positions offered by the 131 nonfederal governmental institutions totaled 3,800 (32%). The 670 nongovernmental hospitals accounted for 7,393 positions (62%). The nine proprietary hospitals offered 59 positions (less than 1%).

---

* Includes 60 positions assigned to the U. S. Air Force.

As in previous years, the highest occupancy rate occurred in the federal hospitals, with an average of 88% positions filled on Sept. 1, 1956; individual federal service figures varied from a low of 58% occupancy in the Veterans Administration hospitals to 100% occupancy in the Army hospitals. The Army figure of 211 positions filled includes 60 internships filled by interns assigned to the Air Force; no Air Force Hospitals conducted intern training programs during the year. Army hospitals being used for training Air Force interns. Occupancy rate for the nonfederal governmental hospitals was 89%, a decrease of 2% from last year's figure; county hospitals had the highest rate (91%) in this group. For the nongovernmental hospitals, the rate was 79%; and that for proprietary institutions was 83%. The over-all occupancy rate for all hospitals offering approved internships was 83%.

TABLE 5.—*Number of Internships, by Medical School Affiliation and Bed Capacity 1956-1957*

Totals	69	694	230	75
Grand totals	852	9,893	2,002	83

The federal hospitals averaged 14.0 interns on duty per hospital; the nonfederal governmental figure was 25.7; for nongovernmental hospitals, 8.8; and for proprietary hospitals, 5.5. The average number of interns on duty per hospital was 11.6, as compared with 11.1 in 1955.

In 1954, 9,066 positions were filled (82%); in 1955, 9,603 positions were filled (83%); and in 1956, 9,893 positions were filled (83%). Internships have increased numerically during the past three years, while the occupancy rate has remained stable.

Internships, by Medical School Affiliation and Bed Capacity

In table 5, hospitals are classified into three categories, based on the degree to which medical schools utilize these hospitals for undergraduate medical education. A "major teaching hospital" is one that is considered by the medical school as being a major unit in its undergraduate clinical clerkship program. The term "minor teaching hospital" refers to a hospital

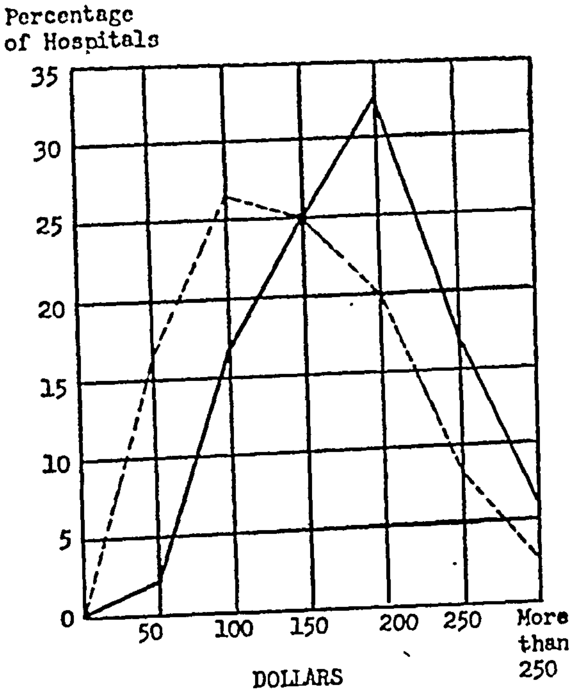
used to a limited extent for undergraduate training. "Nonaffiliated hospitals" are those which are not designated by a medical school as participating in such a program. This classification is used in this report and in the list of approved internships.

Major teaching hospitals (147) constituted 17% of those approved for internships, offered 4,335 internships, and showed an occupancy rate of 89% on Sept. 1, 1956. The 69 minor teaching hospitals were 8% of the total number of hospitals and were 75% filled on the same date. Nonaffiliated hospitals (636), 75% of the approved hospitals, filled 81% of their positions on Sept. 1, 1956.

The major teaching hospital group had the highest occupancy rate (89%), which was the same as the rate for 1955. Nonaffiliated hospitals increased the rate from 79% in 1955 to 81% in 1956.

As was pointed out in the Annual Report for 1955, there was evidenced a definite trend for the larger hospitals to have a higher percentage of internships filled. This observation is again borne out by the figures shown in table 5. For hospitals of 200 beds or less in all three groups, the combined occupancy rate was 77%; for hospitals having 200 to 299 beds, the rate was the same, 77%; hospitals having 300 to 499 beds indicated that 81% of their positions were filled; and hospitals having more than 500 beds showed a 90% occupancy rate.



Monthly internship stipends, with federal hospitals excluded. Solid line indicates nonaffiliated hospitals (606), dashed line affiliated hospitals (204). Abscissa gives upper level of stipend range.

Internships, by Census Region and State

Table 6 shows a breakdown by states and regions of the internships on Sept. 1, 1956, with numbers of positions filled and vacant, and the percentage of internships filled quoted in each instance.

Hospitals in United States territories and possessio again showed the highest percentage of filled positio —97%. The New England region had the highest occ pancy rate for the continental United States, 89 which was an increase of 3% over last year's figu The rate of 72% in the East South Central region w the lowest recorded this year. Individual states havi 90% occupancy or higher were New Hampshire (100%), Rhode Island, New Jersey, New York, Kansas, District of Columbia, Louisiana, New Mexico (100%), Oregon, Canal Zone (100%), Hawaii (100%), and Puerto Rico. Lowest rates were those for Montana and North Dakota.

New Mexico offered an approved internship for the first time. Those states which do not have approved intern training programs at the present time are Idaho Nevada, and Wyoming.

Internship Stipends

Stipends for interns have increased appreciabl during the past several years. The average cas stipend paid the intern in affiliated hospitals dur ing 1954 was $87; in 1955 this figure increased t $121; the stipend for 1956 increased still furthe to reach a figure of $141, an increase of $20 ove 1955. The nonaffiliated hospitals showed a simila increase. Figures for the past three years for non affiliated hospitals are 1954, $136; 1955, $169, an 1956, $177.

In the figure, the graph portrays the internsh stipends for 1956, comparison being made b tween the affiliated and the nonaffiliated instit tions. Federal hospitals are excluded from this grap The curve shown for each type of hospital is r unlike that for the previous year. Only one hos tal reported "No stipend paid"—an affiliated hos tal.

Seventy-three per cent of the affiliated hospi furnished full maintenance, 18% furnished par maintenance, and 9% furnished no maintenan Eighty-five per cent of the nonaffiliated hospi offered full maintenance in addition to the stipe 12% gave partial maintenance; and 3% indicated maintenance furnished.

The stipend paid by the nonaffiliated hospital a aged $36 per month more than was paid by the a ated hospital. The occupancy rate (Sept. 1, 1956) the internships offered by nonaffiliated hospitals 81% compared with a rate of 86% for the affili hospitals. These data might be interpreted to r that the average intern is more interested in (that the average intern is more interested in the fina aspects of the internships than he is in the fina return.

In the list of approved internships, under the co headed "Beginning stipend," the letters FM and refer respectively to "full maintenance" and "p maintenance."

Autopsy Rates

The autopsy rate on hospital deaths is regarded by the Council as an index of the scientific interest of the medical staff in medical education and in the progress of medicine. In table 7 the 20 federal hospitals and the 20 nonfederal hospitals reporting the highest rates for the past year are listed. These hospitals are to be commended for maintaining these rates at a high level.

It is of interest to compare this listing with that of previous years and to note that certain institutions have consistently maintained a high rate. Of the federal hospitals listed, seven are listed for the sixth consecutive year; of the nonfederal hospitals, six have maintained a place on the list for the past six years.

TABLE 7.—*Internship Hospitals with Highest Autopsy Rates 1956*

	Federal	Percent
1.	U. S. Naval Hospital, Corona, Calif.	99

2.	Children's Medical Center, Boston	86
3.	Children's Hospital, Buffalo	86
4.	Milwaukee Children's Hospital, Milwaukee	84
5.	University of Illinois Research and Educational Hospitals, Chicago	84
6.	University of California Hospitals (Herbert C. Moffitt Hospital), San Francisco	83
7.	University of Minnesota Hospitals, Minneapolis	83
8.	Ochsner Foundation Hospital, New Orleans	83
9.	Mary Hitchcock Memorial Hospital, Hanover, N. H.	82
10	Sacred Heart General Hospital, Eugene, Ore.	82
11.	Colorado General Hospital, Denver	82
12.	University Hospitals, Madison, Wis.	81
13	University of California Hospital, Los Angeles	80
14.	University of Nebraska Hospital, Omaha	80
15.	Aguadilla District Hospital, Aguadilla, P. R.	80
16	St. Louis Children's Hospital, St. Louis	79
17.	University Hospital, Ann Arbor, Mich.	77
18.	Virginia Mason Hospital, Seattle	77
19.	Barnes Hospital, St. Louis	76
20.	Evanston Hospital, Evanston, Ill.	76

Of the 852 hospitals reporting, only 5 (less than 1%) failed to meet the minimum autopsy requirements of 25%. These institutions are being urged to increase the rate, as a subminimal rate for two consecutive years may be the basis for withdrawal of approval.

Internship Review Committee

Membership on the Internship Review Committee is composed of representatives from the Council on Medical Education and Hospitals, the Association of American Medical Colleges, the American Hospital Association, the Federation of State Medical Boards of the United States, and the American Academy of General Practice.

The Committee was formed in 1954 to review reports of surveys of intern training programs and make recommendation to the Council for appropriate action. The Committee also may make recommendations to the Council for changes in the requirements for approval of an internship and for changes in policy concerning the education of interns.

Since the Committee was established, it has advocated that the Essentials of an Approved Internship be interpreted with reasonable flexibility. It has followed the policy of giving a hospital an opportunity to correct deficiencies found on survey before approval is actually withdrawn; the hospital is advised concerning the nature of the deficiencies and is encouraged to correct them as quickly as possible.

The objective toward which the Committee is working is to maintain and improve the standards of medical education at the internship level.

National Intern Matching Program

The National Intern Matching Program continues to serve as the central clearing agency for hospitals seeking interns and for medical students desiring internships. For the past six years, hospitals approved for intern training by the Council on Medical Education and Hospitals and medical students seeking first year internships have used the NIMP as the official agency for intern procurement. The plan gives complete freedom of choice to both hospitals and students and has received continued support from both groups.

Hospitals approved by the Council submit a Hospital Agreement to the Program in which they agree to interview only students who participate in the program and to accept all interns matched to them. Students submit similar agreements, stating they will apply only to participating hospitals and will accept the hospital to which they are matched. Hospitals and students make contact with each other by means of the NIMP Directory. Hospitals receive a Directory of all participating students, and students receive a hospital Directory in which are listed all participating hospitals and the type and number of internships each offers. Hospitals are free to interview as many applicants as possible, using any means of evaluation they desire.

The Matching Program has matched more than 35,000 students with no reported error to date. The policies and general management of the program are governed by the organizations most interested in medical education at the intern level. These organizations include, in addition to the Council on Medical Education and Hospitals, the American Hospital Association, the Association of American Medical Col-

Residencies, by Type of Hospital Control

A breakdown of residency appointment by type of hospital control is presented in table 9. Residency programs were offered in 119 federal hospitals, 314 other governmental (nonfederal) hospitals. 741 nongovernment institutions, and 25 proprietary hospitals. The total number of residencies was almost equally divided between governmental and nongovernmental hospitals, with the former having a total of 14,264 appointments, and the latter 14,177. The Veterans Administration offered 3,150 of the 4,249 appointments in federal hospitals.

Grand totals	1,199	5,131	9,158	2,492	79	23,012	5,516	81

Number of Residencies, by Hospital Bed Capacities

Excluding hospitals of less than 200 beds the hospitals offering residency training are, roughly speaking, divided into three categories/200-299 bed capacity, 300-499, and over 500 beds (table 10), with about 300 hospitals in each group. Seventy-five hospitals with less than 100 bed capacity and 205 with capacities of 100-199 beds offer approved programs. Approximately 92% of the positions offered are in hospitals of 200 or more bed capacity, and approximately 52% are in hospitals with 500 or more beds.

On the basis of such data as are available, it appears that the number of residencies is generally proportionate to the size of the hospital. However, these data do not eliminate the possibility that an individual hospital or individual service may have a disproportionately large resident staff.

RÉSUMÉ

This 31st Annual Report presents factual data on approved internships and residencies, primarily to assist medical students, interns, and residents in determining where they wish to continue their medical education. The report includes an analysis of statistical tables and graphs, in addition to information regarding the National Intern Matching Program, the Internship and Residency Review Committees, and a discussion of the straight internship. Following the report, complete lists of approved intern and residency training programs are published.

A total of 6,635 training programs at the graduat level (internships and residencies) were offered i 1,372 hospitals on Sept. 1, 1956. Of this number hospitals, 156 offered approved intern training onl 513 offered approved resident training only; and 70 gave both intern and resident training. The numb of approved intern positions has increased from 11,6 to 11,895 (2%) during the past year. Residency po tions increased from 26,516 to 28,528 (8%) during t same period.

There was no appreciable change in the percenta of internships filled—83% for this year and also for t previous year. The occupancy rate for residency po tions on Sept. 1, 1956, was 81%, as compared with t same figure of 81% for the previous year.

The status of straight internships has been clarifi The Council will continue to approve straight inte ships in medicine, surgery, pediatrics, and pathology. It will also approve straight internships in obstetrics-gynecology when these programs are of superior educational content and comprehensive scope.

Residency Review Committees are functioning effectively in 16 specialty fields and in General Practice. There are no Residency Review Committees in three specialties. Graduate training has been offered in 29 fields.

The Council has presented this Annual Report in the hope that it will be of assistance to all individuals and organizations interested in medical education at the graduate level.

APPROVED INTERNSHIPS

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to September 1, 1957

HOSPITALS, 854, INTERNSHIPS, 12,404

The following general hospitals, investigated and approved by the Council on Medical Education and Hospitals, are considered in position to furnish acceptable intern training in accordance with standards adopted by the American Medical Association. Three types of internships are approved by the Council—rotating, mixed, and straight:

1. A rotating internship is defined as one that provides supervised experience in internal medicine, surgery, pediatrics, obstetrics, and their related subspecialties, together with experience in laboratory and radiologic diagnosis.

2. A mixed internship is defined as one that provides supervised experience in two or more, but not in all, of the clinical divisions named.

3. A straight internship is defined as one that provides supervised experience in a single department, although it may include limited opportunity for work in a related subspecialty. Straight internships are now approved in internal medicine, surgery, pediatrics, pathology, and obstetrics-gynecology.

Hospitals approved for internships that are used by medical schools for undergraduate clinical clerkships on inpatient services have been identified in the following lists by the symbols X and x. Hospitals have been identified with symbol X when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with the symbol x when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program. Certain internships in hospitals designated as teaching hospitals may not provide for assignments to teaching services. Other internships may provide for only a portion of the internship period being spent on teaching services. Prospective interns desiring specific information concerning internship assignments to teaching services in a hospital are advised to communicate with the dean of the medical school with which the hospital is affiliated. Medical school affiliations are indicated by footnotes 10 to 89 placed immediately after the symbol X or x. The list of medical schools appears on page 482. The plus (+) sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables. When applying for internships in Air Force, Army, Navy or Public Health Service hospitals, applications should be directed to the medical departments of the Air Force, Army, Navy, or the United States Public Health Service and not to the individual hospitals. Although applications are made to the service rather than to the individual hospitals, all of the services ask students to list three hospitals in order of preference. Every possible effort is made to place successful candidates in accordance with their desires. Because of the needs of the service it should be understood that students may, in some instances, be assigned to other hospitals than those for which they have indicated a preference.

Hospitals listed below (pages 461 to 481) make first year internship appointments through the National Intern Matching Program, Inc. The number and type of internships as listed represent appointments for the intern year 1958-1959.

Hospitals designated with an asterisk (*) in this listing do not participate in the National Intern Matching Program, sponsored by the Medical Association, the American Hospital Association, the Association of American Medical Co [illegible] and other cooperating organizations. Abbreviations and other references will be found on pages 482 and 483.

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

The following list of hospitals that conform to the standards of the Canadian Medical Association is published for the information of [illegible] interested in an internship appointment in a Canadian hospital. Hospitals that are unqualifiedly approved as conforming to the standards [illegible] Canadian Medical Association may be considered as offering internships equivalent in educational value to those in hospitals approved [illegible] training by the Council.

This list, revised to Sept. 1, 1956, was furnished by the Canadian Medical Association.

Name of Hospital	Location
Royal Columbian Hosp.	New Westminster, B. C.
Trail-Tada[illegible]	Trail, B. C.
St. Paul's [illegible]	[illegible]uver, B. C.
Vancouver [illegible]	[illegible]ouver, B. C.

ABBREVIATIONS AND NOTES

1. Appointments available to women applicants
2. Appointments restricted to women applicants
3. Appointments available to graduates of foreign medical schools. Details regarding requirements for appointment can be secured from the hospitals concerned.
4. Dental internships available
5. Available to citizens of the United States only

+ The plus sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships

CyCo	City and County
Corp	Corporation unrestricted as to profit
Dist	Hospital District
NPCorp	Nonprofit corporation
Part	Partnership
Req	Required
FM	Full maintenance
PM	Partial maintenance

Medical School Affiliations

Footnotes 10 to 89 refer to medical schools affiliated with hospitals for undergraduate clinical clerkships.

Hospitals have been identified with symbol **X** when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with symbol **x** when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program

APPROVED RESIDENCIES AND FELLOWSHIPS

Council on Medical Education and Hospitals of the American Medical Association

535 North Dearborn Street, Chicago 10

Revised to September 1, 1957

Hospitals, 1,259; Assistant Residencies and Fellowships, 31,252

The following services are approved by the Council on Medical Education and Hospitals as meeting the requirements of the Essentials of Approved Residencies and Fellowships. In those specialties in which certifying boards have been established approval is extended in concurrence with the Board concerned as indicated. The number of years of training for which approval has been granted is indicated in the column, "Length of Approved Program (years)." Residencies in which this designation does not appear have been approved without specifying the number of years for which they are accredited. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables.

Residency programs in the following hospitals have been approved by the Council and the American Board of Orthopedic Surgery, through the Residency Review Committee for Orthopedic Surgery, as offering acceptable training in adult orthopedics and fractures. Training in the basic sciences is given as an integral part of these services or as a separate course. Services collaborating in an integral plan of training are designated by a program number, a list of which is found on pages 519 and 520.

Residents completing three years of training in Adult Orthopedics and Fractures at these hospitals are eligible for limited certification by the American Board of Orthopedic Surgery, not to include children's orthopedic surgery.

17. PATHOLOGY

Residency programs in the following hospitals have been approved by the Council and the American Board of Pathology as offering acceptable training in the specialty. Services which have been evaluated on the basis of training in the two categories, pathologic anatomy and clinical pathology, are designated as follows: a—pathologic anatomy only; c—clinical pathology only; p—pathologic anatomy and clinical pathology.

Hospitals, 633; Assistant Residencies and Residencies, 2415

21. PREVENTIVE MEDICINE

AVIATION MEDICINE

The following programs in Aviation Medicine have been approved by the Council and the American Board of *Preventive Medicine*, through the Residency Review Committee for Preventive Medicine, as offering acceptable training in the specialty.

School	Location	Director		Length of Approved Program (Years)	Beginning Stipend (Month)
UNITED STATES AIR FORCE					
Wright-Patterson Air Force Base	Dayton, Ohio	W F Hall	For information regarding program, write to Chief, Medical Division Office Surgeon General, U S A F, Washington 25, D C	1	
School of Aviation Medicine	Randolph Field, Texas	O O Benson, Jr	For information regarding program, write to Chief, Medical Division Office Surgeon General, U S A F, Washington 25, D C		
UNITED STATES NAVY					
School of Aviation Medicine	Pensacola, Fla	J C. Early-A Graybiel	For information regarding program, write to Director, Graduate Medical Training Bureau of Medicine and Surgery, U S Navy, Washington 25, D C	2	
NONFEDERAL					
Ohio State University Medical Center	Columbus, Ohio	W F Ashe		3	3

OCCUPATIONAL MEDICINE

The following educational institutions have been approved by the Council and the American Board of Preventive Medicine, through the Residency Review Committee for Preventive Medicine, for THREE years of training in Occupational Medicine. The academic portion of these residencies will be given in the institutions listed. *The inplant training is being arranged. For further detailed information concerning a program, it is suggested that the applicant write to the physician in charge of the particular program concerned.*

	Location	Physician in charge
University of Rochester School of Medicine and Dentistry	Rochester, N Y	J H Sterner
University of Cincinnati Institute of Industrial Health, College of Medicine	Cincinnati	R A Kehoe
Ohio State University Medical Center, Department of Preventive Medicine	Columbus, Ohio	W F Ashe
University of Pittsburgh, Graduate School of Public Health	Pittsburgh	A G Kammer

PUBLIC HEALTH

Residency programs in Public Health in the following states have been approved for TWO years of training by the Council and the *American Board of Preventive Medicine, through the Residency Review Committee for Preventive Medicine.*

Department of Health	Location	Director	Local Areas	Population	Stipend (Month)
State of California	Berkeley	M H Merrill	San Diego County (a)	876,000*	$481
State of Delaware	Dover	F I Hudson	Kent and New Castle Counties (b)	190,000*	$400-460
State of Florida	Jacksonville	W T Sowder	Alachua County	65,900*	$500 (c)
			Dade Miami	757,700*	
			Hillsborough-Tampa	332,600*	
			Pinellas St Petersburg	235,700*	
State of Illinois	Springfield	R R Cross	Cook County (d) (e)	743,988	$410-460
			Peoria (City) and Peoria County (e) (o)	174,347	
			Will County (e)	134,366	
State of Kansas	Topeka	T R Hood	Kansas City-Wyandotte	189,000	(f) (r)
			Topeka Shawnee	115,006	
			Wichita Sedgwick	297,388	
State of Maryland	Baltimore	E Davens	Anne Arundel County	171,700*	$411
			Baltimore City	974 000*	
			Baltimore County	370,400*	
			Montgomery County	256,500*	
			Washington County	85,700*	
State of Michigan	Lansing	A L Heustis	Calhoun County	123,230	$400
			Detroit	1,966,270	
			Michigan Dept of Health	(m)	
State of Minnesota	Minneapolis	R N Barr, Secy and Ex Off	Minneapolis City	542 000*	$400
			Olmstead-Rochester	48,395	
			(n)		
New York City	New York City	R P Kandle, Dep Com		8,010,000	$443
State of New York	Albany	H E Hilleboe	(l)	941,000	$475
State of North Carolina	Raleigh	J W R Norton	Charlotte Mecklenburg County	225,321	$417
			Forsyth Winston Salem	158,422	
			Halifax	59,539	
			Orange Pearson Chatham Lee	117,797	
			Pitt	65,377	
State of Oregon	Portland	H M Erickson	Multnomah County	119 720*	$300 (f)
State of Texas	Austin	F C Kluth	(g)	596 163*	$400 (f)
State of Virginia	Richmond	M I Shanholtz	Arlington County	163 000*	$270
State of Washington	Seattle	B Bucove	*Bremerton* Kitsap		$460
			Clark Skamania	91,100*	
			King Seattle	818 700*	
			Spokane City		
			Tacoma-Pierce		

---

* Estimated

(a) Two other local departments not yet selected

(b) Excludes the city of Wilmington

(c) To those planning to work in state; transportation costs only to others

(d) Excludes Berwyn, Chicago, Evanston, Oak Park, Stickney Township, and Winnetka (including *Glencoe*, Kenilworth, Northbrook, and *remainder of* New Trier Township), all with full time health *officers*

(e) Assistance can be arranged *for securing the* MPH degree in the midst of, or after completion of, residency experience *Appointments* normally are limited to those training for service in Illinois Exceptions may be made in *special cases*

Numerical and other references will be found on pages 556 through 559.

(f) Arrangements for remuneration made on an individual basis.

(g) 42 city-county or county health departments and 5 city health departments in which training may be given depending upon local conditions and the needs and desires of the resident.

(h) Training is given in a combination of one county, one union health, and seven municipal health departments and in the divisions of the State Department of Health.

(i) Assistance can be arranged for securing the MPH degree after successful completion of residency experience. Appointments will be limited to those training for service in Oregon.

(j) Excludes Detroit and Dearborn, each with full-time health officers.

(k) To those training for service in Minnesota only.

(l) Training is given in any one of 10 city health departments, 16 county health departments, or 15 district offices within the state.

(m) Training to be with Michigan Department of Health, with field experience in local health departments.

(n) Includes training at Montefiore Hospital.

(o) Training is given under one director in both the City and County Health Departments.

(p) Stipend offered only to those residents who plan to remain in public health work in the state at least six years.

(r) Arrangements for remuneration made upon determination of field of interest and location desired.

22. PROCTOLOGY

Residency programs in the following hospitals have been approved by the Council and the American Board of Proctology, through the Residency Review Committee for Proctology, as offering acceptable training in the specialty.

Hospitals, 13; Assistant Residencies and Residencies, 33

Name of Hospital	Location	Chief of Service	Inpatients Treated	Autopsies	First Year Residencies Offered*	Total Residencies Offered*	Length of Approved Program (Years)	Beginning Stipend (Month)

PSYCHIATRY PROGRAM IDENTIFICATION

10 Service in child psychiatry
11 Six months service at Los Angeles County Hospital Los Angeles
12 Nine months service at Mount Zion Hospital six months at Langley Porter Clinic and service in child psychiatry, San Francisco
13 Three months of service at Napa State Hospital San Francisco Hospital Stockton State Hospital Sonoma State Home and San Quentin Prison and six months at Colwell Memorial Hospital
14 Three months service at Fort Miley Veterans Administration Hospital San Francisco and Langley Porter Clinic San Francisco, may include elective services at University of California Hospital Mount Zion Hospital and Stanford University (Lane) Hospital San Francisco
15 Three months service at Pacific Colony Hospital Pomona and three months service in child psychiatry at Camarillo State Hospital
16 Affiliate service at Colorado General and Denver General Hospital
17 Affiliate service at Veterans Administration Hospital West Haven Connecticut State Hospital Fairfield State Hospital, Norwich State Hospital and service in child psychiatry
18 Twelve months service at Grace New Haven Community Hospital, New Haven Connecticut
19 Six month service at Governor Bacon Health Center, Delaware City
20 Two months service at George Washington University Hospital Washington D C
21 Affiliate service at University Hospital Augusta, Georgia
22 Twelve month service at the Neuropsychiatric Institute of the University of Illinois including service in child psychiatry
23 Eighteen month affiliate service including service at the Neuropsychiatric Institute of the University of Illinois and three months in child psychiatry
24 Affiliate service at Neuropsychiatric Institute of the University of Illinois and service in child psychiatry
25 Three months service at Veterans Administration Hospital Downey, Illinois and service in child psychiatry
26 Six months service at Veterans Administration Hospital Hines Illinois May include service in child psychiatry
27 Six months service in child psychiatry
28 Integrated program including service at Veterans Administration Hospital Indianapolis General Hospital and Indiana University Medical Center and Affiliated Hospitals, Indianapolis
29 Integrated program including service at Veterans Administration Hospital Menninger Sanitarium and Topeka State Hospital Topeka Kansas
30 Four months service at University of Louisville Services, Louisville Kentucky, and four months service at Cincinnati General Hospital Cincinnati Ohio
31 Three months service at University of Louisville Services Louisville Kentucky
32 Twelve months service at University of Louisville Services May include four months service at Central State Hospital four month service at Louisville General Hospital
33 Four months service at Central State Hospital and service in child psychiatry
34 Integrated program including service at Tulane University Unit Charity Hospital New Orleans, and Veterans Administration Hospitals New Orleans and Biloxi, Mississippi
35 Six months service in child psychiatry and twelve months service at South Louisiana State Hospital
36 Service in child psychiatry
37 Three months service in child psychiatry at Johns Hopkins Hospital (Harriet Lane House), Baltimore, Maryland
38 Twelve months service at Boston State Hospital and service in child psychiatry
39 Twelve-eighteen months service at Veterans Administration Hospital Boston (Jamaica Plain) Massachusetts and six months service in child psychiatry
40 Integrated program including service at Massachusetts General Hospital and McLean Hospital Waverly, may include 1 year training in child psychiatry at James Jackson Putnam Children's Center
41 Twelve months service at University Hospital Ann Arbor Michigan
42 University Hospital Ann Arbor Michigan
43 Three months service at Coldwater State Home and Training School Caro State and Ionia State Hospitals and service in child psychiatry
44 Six months service in child psychiatry at Children's Hospital Detroit
45 Six months service at Receiving Hospital, Children's Hospital, Detroit, and Wayne County General Hospital and Infirmary, Eloise, Michigan
46 University of Minnesota Hospitals Minneapolis, Minnesota
47 Three months service at Rochester State Hospital, Rochester, Minn
48 Affiliate service at Barnes Hospital St Louis and three months at St Louis State Hospital
49 Six months service at Barnes Hospital, St Louis, Missouri
50 Service at St Louis State Hospital and St Louis City Hospital.
51 Service at Lutheran Hospital, Omaha
52 Service at University of Nebraska Hospital
53 Affiliate service at University of Nebraska Hospital and Creighton Memorial St Joseph Hospital, Omaha Nebraska
54 Six months service at Newark City Hospital three months at New Jersey State Hospital and three months in child psychiatry
55 Three months service at Albany Hospital Albany New York
56 Affiliate services at Edward J Meyer Memorial Hospital and Buffalo State Hospital
57 Six months service at Kings County Hospital Brooklyn, New York
58 Integrated program with service at Bellevue Hospital Center and University Hospital
59 Six months service at Mount Sinai Hospital New York City
60 Service in child psychiatry May include six months service at Mount Sinai Hospital and three months at Manhattan State Hospital
61 Twelve months service at New York Hospital and four months at Veterans Administration Hospital, New York City (Bronx), New York
62 Three months service at Grasslands Rockland State, Albany Hospitals and Letchworth Village
63 Six months service at Rochester State Hospital, Rochester, New York
64 Six months service at Strong Memorial Rochester Municipal Hospitals, Rochester
65 Affiliate service at Strong Memorial Rochester Municipal Hospitals
66 Three months service at Syracuse Memorial, Binghamton, Syracuse and Willard State Hospitals, service at Craig Colony and service in child psychiatry
67 Affiliate service at State Hospitals at Raleigh and Butner, North Carolina
68 Eighteen months service at Duke Hospital Durham, North Carolina
69 Three months service at Longview State and Jewish Hospitals, Cincinnati
70 Integrated program including service at Cleveland Clinic and Windsor Hospital
71 Integrated program including service at University Hospital and Veterans Administration Hospital Cleveland, Ohio
72 Integrated program with service at Institute of the Pennsylvania Hospital and Pennsylvania Hospital Department for Mental and Nervous Diseases
73 Affiliate service at Temple University Hospital Institute of Pennsylvania Hospital of the Woman's Medical College of Pennsylvania
74 Six months service at Philadelphia General Hospital and service in child psychiatry
75 Two months affiliate service for institutional care
76 Integrated program including service at Vanderbilt University Hospital, Veterans Administration Hospital, Nashville, Veterans Administration Hospital Murfreesboro and Central State Hospital Nashville
77 Four months affiliate service at St Mary's Infirmary, Galveston, Texas
78 Service in child psychiatry at Jefferson Davis Hospital Houston Texas
79 Six months affiliate service at Veterans Administration Hospital Salt Lake City, Utah and affiliate services at State Hospital, Provo, Utah
80 Integrated program including service at University of Virginia Hospital, Charlottesville and Veterans Administration Hospital Roanoke, Va
81 Affiliate service at Southwestern State Hospital Marion and Lynchburg State Colony, Lynchburg Va
82 Six months service at Medical College of Virginia—Hospital Division, Richmond, and service in child psychiatry
83 Six months service at Veterans Administration Hospital American Lake, Washington, and six months in child psychiatry

28. UROLOGY

Residency programs in the following hospitals have been approved by the Council and the American Board of Urology, through the Residency Review Committee for Urology. These programs are approved for THREE years of training. All hospitals listed offer three years of training intramurally or on an integrated basis through affiliation with another approved institution.

Hospitals, 233; Assistant Residencies and Residencies, 708

NUMERICAL AND OTHER REFERENCES

1. Appointments available to women applicants.
2. Appointments available to women applicants only
3. Appointments available to graduates of foreign medical schools
8. Includes fellowships.
10. Training at the third year level only.
12. May include one year fellowships in the Department of Cardiology.
13. May include one year of training at Cook County Hospital, Chicago, by special arrangement.
14. May include one year of surgical research at Louisiana State University School of Medicine.
15. Training limited to Contagious Diseases.
16. Approved for affiliate training only.
17. Formerly New York City Hospital, New York, N. Y.
18. Combined integrated program—Bellevue, Div. II (Cornell and Memorial Cancer Center)
19. Training in pediatric psychiatry (third year level)
20. To include one year of affiliate training at the second year level at the University Hospitals (Lakeside) Cleveland.
21. This one year of training is equivalent to one year of basic science as a part of an approved three year program.
22. University of Texas coordinates program of three years' duration.
23. An additional one year of fellowship training in cardio-pulmonary laboratory is available.
24. Includes one year of training at Veterans Administration Hospital, Iowa City
25. Provides training at the third year level, affiliate training with University of Minnesota Hospitals, Minneapolis, Minn.
26. Approved for affiliate training only.
27. Obstetrical and Gynecological pathology only.
28. Special pathology as a part of pathologic anatomy. See Board requirements.
29. Category P. Am. Bd. of Pathology. See Page 584.
30. LaRabida Sanitarium, Lewis Memorial Maternity Hospital, Contagious Disease Hospital, St. Joseph Hospital, St. Vincent's H pital, Chicago.
31. Methodist Hospital and St. Francis Hospital Divisions.
32. Approved for one year of training in Hematology as a part of addition to the residency training program in Internal Medicine.
33. Affiliate rotation at Yale-New Haven Medical Center, Grace-N Haven Community Hospital.
34. Six months of training is afforded at University Hospitals, Io City, Iowa.
35. Offer training at the third year level only.
36. Provides training at the 3rd year level, affiliated with University Minnesota Hospital, Minneapolis, Minn.
37. Includes one year of training at Parkland Memorial Hospital, Dal Texas.
38. Approved for training at the first year level.
39. One year affiliation available at Veterans Admin. Hospital, I City, Iowa.
40. Approved for one year of training equivalent to one year of b science as a part of an approved three year program.

REQUIREMENTS FOR CERTIFICATION

AMERICAN SPECIALTY BOARDS

Examining and certifying boards in 19 specialties have been approved by the Council on Medical Education and Hospitals of the American Medical Association and the Advisory Board for Medical Specialties on the basis of minimal standards governing accreditation of specialty boards as formulated by the Council.

The primary purposes of the boards are (1) to conduct investigations and examinations to determine the competence of voluntary candidates for certificates issued by the respective boards, (2) to grant and issue certificates of qualification to candidates successful in demonstrating their proficiency, (3) to stimulate the development of adequate training facilities, (4) to aid in evaluating residencies and fellowships under consideration by the Council on Medical Education and Hospitals of the American Medical Association, and (5) to advise physicians desiring certification as to the course of study and training to be pursued.

The boards are in no sense educational institutions, and the certificate of a board is not to be considered a degree. It does not confer on any person legal qualifications, privileges, or a license to practice medicine or a specialty. The boards do not purport in any way to interfere with or limit the professional activities of any licensed physician, nor do they desire to interfere with any practitioners of medicine in any of their regular or legitimate duties.

Two boards certify candidates in subspecialties. The American Board of Internal Medicine certifies in allergy, cardiovascular disease, gastroenterology, and pulmonary diseases. The American Board of Pediatrics certifies in allergy. Certification in the primary field is a requirement for certification in the subspecialties. The Board of Thoracic Surgery, which is organized as an affiliate board of the American Board of Surgery, requires certification in surgery as a prerequisite to certification in thoracic surgery.

Certificates in special divisions of their specialty are conferred by six boards. The American Board of Obstetrics and Gynecology will issue certificates in obstetrics or gynecology only. The American Board of Otolaryngology grants a limited certificate in endoscopy. The American Board of Pathology issues certificates in pathological anatomy, clinical pathology, a combination of these two fields, pathological anatomy and clinical microbiology, clinical microbiology and clinical chemistry, clinical bacteriology, neuropathology, clinical microbiology, hematology, and clinical chemistry. The American Board of Preventive Medicine issues certificates in public health, aviation medicine, and occupational medicine. The American Board of Psychiatry and Neurology issues separate certificates in psychiatry and in neurology, or a combined certificate for those qualified in both fields. This board also issues supplementary certificates in psychiatry and in neurology. The American Board of Radiology issues certificates in radiology, roentgenology, therapeutic radiology, diagnostic roentgenology, therapeutic roentgenology, radium therapy, radiological physics, x-ray and radium physics, and medical nuclear physics.

The majority of the American specialty boards have published booklets containing a list of their officers together with statements regarding organization, purposes, and qualifications that determine eligibility for certification. In this issue of The Journal, there are published, with the consent of each board concerned, the requirements for certification in specialties. This information is published for the convenience of those physicians who are planning to seek board certification. Any specific inquiry concerning certification by a specialty board should be addressed to the board secretary, whose name and address will be found in this issue of The Journal.

Table 1 contains a list of the approved specialty boards, the year of activation, and the total number of candidates certified through June 30, 1957. Data are also presented regarding the number of physicians certified in the subspecialties and those granted special certification by the boards in obstetrics and gynecology, otolaryngology, pathology, preventive medicine, psychiatry and neurology, and radiology.

Table 1.—*Approved Examining Boards in Medical Specialties*

Name of Board	Year of Activation	Total Certificates Awarded to June 30, 1957
American Board of Anesthesiology	1937	1,698
American Board of Dermatology	1932	1,846
American Board of Internal Medicine	1936	11,336
American Board of Neurological Surgery	1940	715

---

* Independent board established in 1949

A total of 63,727 physicians were reported certified by the 19 specialty boards on July 1, 1956. From this date through June 30, 1957, 5,424 physicians were certified, bringing the total to 69,151 certifications on June 30, 1957. Eighty-six physicians were certified in the subspecialties, bringing that total to 1,509 on the same date.

Table 2 indicates the total number of physicians certified each year for the past 15 years by all specialty boards. The total number certified on June 30, 1957, was 69,151.

The eighth edition of the "Directory of Medical Specialists," compiled by the Advisory Board for Medical Specialties and published in 1957 by the A. N. Marquis Company, Chicago, contains biographic information on the educational background of each living specialist, including those retired from practice, certified by an American board.

AMERICAN BOARD OF ANESTHESIOLOGY

Donald L. Burdick, President
New York
Frederick P. Haugen, Vice President
Portland, Ore.
Stuart C. Cullen, Iowa City
Robert B. Dripps, Philadelphia
Albert Faulconer, Rochester, Minn.
Forrest E. Leffingell, Pasadena, Calif.
E. M. Papper, New York
Milton C. Peterson, Kansas City, Mo.
Harvey C. Slocum, Washington, D. C.
Scott M. Smith, Salt Lake City
Curtiss B. Hickcox, Secretary-Treasurer, 80 Seymour St., Hartford, Conn.

The regulations of this specialty board are undergoing revision at this time. For current requirements for certification, communications should be addressed to the Secretary of the American Board of Anesthesiology.

Table 2.—*Annual Specialty Board Certification, 1942-1957*

Year (Ended March)	No. of Boards in Existence	No. Certified	Cumulative Totals
1942	15	1,756	19,694
1943	15	2,172	21,866
1944	15	1,578	23,444
1945	15	1,308	24,752
1946	15	1,320	26,072
1947	15	2,424	28,496
1948	16	3,002	31,498
1949 (June 30)	19*	4,479	35,977
1950 (June 30)	19	3,827	39,804
1951 (June 30)	19	4,552	44,346
1952 (June 30)	19	4,118	48,464
1953 (June 30)	19	4,022	52,486
1954 (June 30)	19	4,133	56,619
1955 (June 30)	19	3,843	60,644
1956 (June 30)	19	3,083	63,727
1957 (June 30)	19	5,424	69,151

* One board, the American Board of Proctology, did not certify any candidates during this period.

AMERICAN BOARD OF DERMATOLOGY

John H. Lamb, President
Oklahoma City
J. Lamar Callaway, Vice President
Durham, N. C.
Marcus R. Caro, Chicago
Arthur C. Curtis, Ann Arbor, Mich.
Clinton W. Lane, St. Louis
Frances W. Lynch, St. Paul
J. Walter Wilson, Los Angeles
Beatrice Maher Kesten, Secretary, 1 Haven Ave., New York 32, N. Y.
Walter C. Lobitz Jr., Assistant Secretary, Hanover, N. H.

For current requirements for certification, communications should be addressed to the Secretary of the American Board of Dermatology.

AMERICAN BOARD OF INTERNAL MEDICINE

Thomas M. Durant, Chairman, Philadelphia
Howard P. Lewis, Vice-Chairman, Portland, Ore.
Wright R. Adams, Chicago
Thomas H. Brem, Los Angeles
George E. Burch, New Orleans
Hugh R. Butt, Rochester, Minn.
Franklin M. Hanger, New York
Chester M. Jones, Boston
John Minor, Washington, D. C.
George A. Perera, New York
Albert M. Snell, Palo Alto, Calif.
Victor W. Logan, Rochester, N. Y.
Thomas Findley, Secretary-Treasurer, Augusta, Ga.
William A. Werrell, Executive Secretary-Treasurer, 1 W. Main St., Madison, Wis.

Sub-Specialty Boards

Allergy

Vincent J. Derbes, New Orleans
Samuel M. Feinberg, Chicago
Stanley F. Hampton, St. Louis
Francis C. Lowell, Boston
William B. Sherman, New York

Cardiovascular Disease

Charles A. R. Connor, New York
A. Carlton Ernstene, Cleveland
Frank B. Kelly Sr., Chicago
J. Murray Kinsman, Louisville, Ky.
Bruce Logue, Atlanta, Ga.
Richard H. Lyons, Syracuse, N. Y.
Raymond D. Pruitt, Rochester, Minn.

Gastro-Enterology

Leon Schiff, Cincinnati
Lowell D. Snorf, Evanston, Ill.
Henry J. Tumen, Philadelphia
C. Wilmer Wirts, Philadelphia
Eric E. Wollaeger, Rochester, Minn.

Pulmonary Diseases

Alvis E. Greer, Houston, Texas
Roger S. Mitchell Jr., Denver
Edward S. Ray, Richmond, Va.
David T. Smith, Durham, N. C.
Julius L. Wilson, Philadelphia

GENERAL QUALIFICATIONS

1. All candidates must be citizens of the United States or Canada.
2. All candidates must be licensed to practice medicine in a state, territory, or possession of the United States or Canada.
3. All candidates must present evidence of satisfactory moral and ethical standing in the medical profession.

PROFESSIONAL QUALIFICATIONS

1. Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association at the date of graduation.
2. Satisfactory completion of an approved internship of not less than twelve months.*
3. Residency or fellowship approved by the Council on Medical Education and Hospitals of the American Medical Association in internal medicine according to the following plan (Plan A) or one of the alternate plans described under paragraph 4.

---

* During the period in which the 9-9-9 program was in effect an approved internship of nine months will satisfy the requirement of twelve months. A residency of nine months is considered as nine months only.

(Plan A) A residency or fellowship in internal medicine for a *period* of not less than three years in a hospital or other institution approved by the Council on Medical Education and Hospitals of the American Medical Association for residency or fellowship in internal medicine. In such instances in which a resident's nominal status differs from that of the other hospital residents, he must furnish the Board with certification by the Chief of the Medical Service and the Medical Director of the Hospital that he actually performed the full duties of a resident as a bonafide member of the residency program. In addition, two years of adequate *clinical experience in the practice of* internal medicine following graduate training will be required. The Board will accept the following equivalents as satisfying one year only, of the three years of residency or fellowship to which this paragraph refers. (Two years must be in the field of general internal medicine.)

(a) If twelve months of a two year approved internship in a hospital approved for residency training in internal medicine is limited to the medical service and the medical specialties, credit will be granted for a first year of assistant residency. The remaining two years of residency training must be in the general field of internal medicine. Certification by the Chief of the Medical Service as to compliance with this requirement must accompany application.

(b) One year of approved residency in one of the medical specialties: Allergy, Cardiovascular Disease, Gastro-Enterology, Hematology, Pathology, Pulmonary Diseases, Neurology, Pediatrics, Psychiatry, Dermatology and Syphilology, *or one* year of an approved General Practice residency provided the *candidate completes in addition, two full years* of approved residency in the general field of internal medicine.

(c) One year as a graduate student or as an instructor in an approved medical school on a full time basis in Bacteriology, Biochemistry, Pathology, Pharmacology, Physiology, or Internal Medicine.

(d) An advanced degree in the Medical Sciences, provided the work has been done and the degree obtained after graduation from medical school.

Note: Graduate training credit for the time involved will be allowed candidates who take and satisfactorily complete post-graduate courses in internal medicine or the basic medical sciences provided by accredited medical schools on a full time basis. *This ruling shall not apply to courses* of less than three months or more than twelve months duration. A certification of creditable performance, based in part, at least, on a formal examination upon completion of the course, will be required.

Note: Fellowship or Research assignments not approved by the Council on Medical Education and Hospitals will require certification by the Chief of Service that such assignment was equivalent in graduate training opportunities and patient responsibilities to that of an approved residency in internal medicine or the sub-specialties recognized by this Board. This certification must be presented before application is filed.

4. Alternate Training Plans: The Board firmly believes that the plan of intensive training prescribed above offers the best opportunity for a young physician to prepare himself to meet his responsibilities as a specialist in internal medicine. It is recognized, however, that capable individuals may accomplish the same result in a longer period of time during which the training is less intensive. The Board realizes that a number of medical graduates cannot follow the shorter and more desirable plan either because suitable residencies are not available, or in some instances because of personal and economic reasons. Accordingly the Board has modified its previous regulations governing eligibility for admission to examination. In doing so the Board has not modified its standards of examination. It has liberalized its eligibility requirements for admission to examination by accepting *half-time formal training,* and the practice of internal medicine under circumstances favorable as to professional and hospital contacts, in lieu of part of the full-time requirements. It is hoped that by this means exceptional individuals may acquire a knowledge of medicine and experience in its application sufficient to qualify for examination.

The program previously described (Plan A), which consists of three years of formal training in an approved residency or its equivalent, following internship, and followed by two additional years in the practice of internal medicine, is recommended by the Board. Variations in this program are now subject to the following regulations.

(a) In all instances, one year of approved internship and one year of approved residency will be required, except as indicated under Plan "G." The graduate training credit of one year heretofore granted as a result of active duty as a commissioned officer in the Armed Forces during the period beginning December 7, 1941, and ending January 1, 1947, and during the Korean emergency beginning June 1, 1950, and ending July 1, 1954, may not be applied *in satisfaction* of the one year of approved residency referred to in Plans D, E. F, *unless the candidate's assignment is considered* by the Board to have been equivalent to an approved residency.

(b) Following *one year of internship* and two years of approved residency, the remaining requirements may be satisfied by:

(Plan B) That is, by two years of half-time formal training followed by two years of practice limited to internal medicine, or by

(Plan C) That is, by five years of practice limited to internal medicine.

(c) Following one year of internship and one year of approved residency, the remaining requirements may be satisfied by:

(Plan D)° That is, by four years of half-time formal training followed by two years of practice limited to internal medicine, or by,

(Plan E)° That is, by two years of half-time formal training followed by five years of practice limited to internal medicine, or by

(Plan F) That is, by eight years of practice limited to internal medicine.

(d) (Plan G) Physicians who have practiced internal medicine for twelve years following an approved internship may qualify for the examinations without further training.

(e) (Plan H) In order to liberalize the opportunity for adequate training in terms of the requirements of this Board, a special plan (Plan H) has been designed for those men who have been *specially selected for a career in academic medicine.* This plan is as follows:

"*Admission to the written examination* will be granted to a candidate affiliated with a Class A medical school in the United States or Canada who is *recommended* by the Head of the Department of Medicine of the Medical School as being adequately trained in Internal Medicine, provided the candidate has had at least five years of training following an approved internship. This training must have included direct responsibility for patient care in the broad field of internal medicine. This plan is designed for men who contemplate a career in academic medicine."

It will be the responsibility of Heads of Departments of Medicine to affirm to the American Board of Internal Medicine *that the candidate* is qualified for admission to examination after a minimum of five years of training. It may well be that the Head of the Department will require additional years of training beyond the minimum before stating the qualifications of the candidate to the Board. A candidate thus recommended under *the foregoing provisions* will be examined by the Board in the broad field of internal medicine.

If, *during the period of training* under Plan H, the candidate decides to qualify under one of the other plans of the Board (A to G) credit will be granted on the basis of the requirements of Plans A to G.

Half-time formal training under expanded plans B, D and E is defined as follows:

1. Half-time° as an instructor in clinical medicine in a recognized medical school in the United States or Canada.

2. Half-time° in a research fellowship sponsored by a recognized medical school in the United States or Canada.

3. Half-time° as a graduate student in an approved medical school in the United States or Canada.

5. Practice Requirements: A period of not less than two years (to be completed by the time of the first written examination) of adequate clinical experience in the practice of internal medicine. This requirement may be satisfied by inde-

A total of 63,727 physicians were reported certified by the 19 specialty boards on July 1, 1956. From this date through June 30, 1957, 5,424 physicians were certified, bringing the total to 69,151 certifications on June 30, 1957. Eighty-six physicians were certified in the subspecialties, bringing that total to 1,509 on the same date.

Table 2 indicates the total number of physicians certified each year for the past 15 years by all specialty boards. The total number certified on June 30, 1957, was 69,151.

The eighth edition of the "Directory of Medical Specialists," compiled by the Advisory Board for Medical Specialties and published in 1957 by the A. N. Marquis Company, Chicago, contains biographic information on the educational background of each living specialist, including those retired from practice, certified by an American board.

AMERICAN BOARD OF ANESTHESIOLOGY

Donald L. Burdick, President
New York
Frederick P. Haugen, Vice President
Portland, Ore.
Stuart C. Cullen, Iowa City
Robert B. Dripps, Philadelphia
Albert Faulconer, Rochester, Minn.
Forrest E. Leffingell, Pasadena, Calif.
E. M. Papper, New York
Milton C. Peterson, Kansas City, Mo.
Harvey C. Slocum, Washington, D. C.
Scott M. Smith, Salt Lake City
Curtiss B. Hickcox, Secretary-Treasurer, 80 Seymour St., Hartford, Conn.

The regulations of this specialty board are undergoing revision at this time. For current requirements for certification, communications should be addressed to the Secretary of the American Board of Anesthesiology.

Table 2.—*Annual Specialty Board Certification, 1942-1957*

Year (Ended March)	No. of Boards in Existence	No. Certified	Cumulative Totals
1942	15	1,756	19,694
1943	15	2,172	21,866
1944	15	1,578	23,444
1945	15	1,308	24,752
1946	15	1,320	26,072
1947	15	2,424	28,496
1948	16	3,002	31,498
1949 (June 30)	16*	4,479	35,977
1950 (June 30)	19	3,827	39,804
1951 (June 30)	19	4,552	44,346
1952 (June 30)	19	4,118	48,464
1953 (June 30)	19	4,022	52,486
1954 (June 30)	19	4,133	56,619
1955 (June 30)	19	3,843	60,644
1956 (June 30)	19	3,083	63,727
1957 (June 30)	19	5,424	69,151

* One board, the American Board of Proctology, did not certify any candidates during this period.

AMERICAN BOARD OF DERMATOLOGY

John H. Lamb, President
Oklahoma City
J. Lamar Callaway, Vice President
Durham, N. C.
Marcus R. Caro, Chicago
Arthur C. Curtis, Ann Arbor, Mich.
Clinton W. Lane, St. Louis
Frances W. Lynch, St. Paul
J. Walter Wilson, Los Angeles
Beatrice Maher Kesten, Secretary, 1 Haven Ave., New York 32, N. Y.
Walter C. Lobitz Jr., Assistant Secretary, Hanover, N. H.

For current requirements for certification, communications should be addressed to the Secretary of the American Board of Dermatology.

AMERICAN BOARD OF INTERNAL MEDICINE

Thomas M. Durant, Chairman, Philadelphia
Howard P. Lewis, Vice-Chairman, Portland, Ore.
Wright R. Adams, Chicago
Thomas H. Brem, Los Angeles
George E. Burch, New Orleans
Hugh R. Butt, Rochester, Minn.
Franklin M. Hanger, New York
Chester M. Jones, Boston
John Minor, Washington, D. C.
George A. Perera, New York
Albert M. Snell, Palo Alto, Calif.
Victor W. Logan, Rochester, N. Y.
Thomas Findley, Secretary-Treasurer, Augusta, Ga.
William A. Werrell, Executive Secretary-Treasurer, 1 W. Main St., Madison, Wis.

Sub-Specialty Boards

Allergy
Vincent J. Derbes, New Orleans
Samuel M. Feinberg, Chicago
Stanley F. Hampton, St. Louis
Francis C. Lowell, Boston
William B. Sherman, New York

Cardiovascular Disease
Charles A. R. Connor, New York
A. Carlton Ernstene, Cleveland
Frank B. Kelly Sr., Chicago
J. Murray Kinsman, Louisville, Ky.
Bruce Logue, Atlanta, Ga.
Richard H. Lyons, Syracuse, N. Y.
Raymond D. Pruitt, Rochester, Minn.

Gastro-Enterology
Leon Schiff, Cincinnati
Lowell D. Snorf, Evanston, Ill.
Henry J. Tumen, Philadelphia
C. Wilmer Wirts, Philadelphia
Eric E. Wollaeger, Rochester, Minn.

Pulmonary Diseases
Alvis E. Greer, Houston, Texas
Roger S. Mitchell Jr., Denver
Edward S. Ray, Richmond, Va.
David T. Smith, Durham, N. C.
Julius L. Wilson, Philadelphia

GENERAL QUALIFICATIONS

1. All candidates must be citizens of the United States o Canada.
2. All candidates must be licensed to practice medicine in a state, territory, or possession of the United States or Canad
3. All candidates must present evidence of satisfactory moral and ethical standing in the medical profession.

PROFESSIONAL QUALIFICATIONS

1. Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association at the date of graduation.
2. Satisfactory completion of an approved internship of no less than twelve months.*
3. Residency or fellowship approved by the Council on Medical Education and Hospitals of the American Medical Association in internal medicine according to the following plan (Plan A) or one of the alternate plans described under paragraph 4.

---

*During the period in which the 9-9-9 program was in effect a approved internship of nine months will satisfy the requirement of twelve months. A residency of nine months is considered as nine months only.

in October. This examination is divided into a morning and afternoon period for each of which three hours are allowed. The questions are of the multiple choice type, framed in such manner as the Board elects, and designed to test the candidate's basic clinical acumen and his knowledge of applied physiology, anatomy, physiological chemistry, pathology, bacteriology, and pharmacology as related to internal medicine.

2. Candidates must pass the written examination before admission to the oral examination will be authorized. Oral examinations are held near the time and place of the annual meetings of the American Medical Association and the American College of Physicians and at such other times and places as the Board may designate. Announcements of all oral examinations will appear in the *Annals of Internal Medicine* and THE JOURNAL of the American Medical Association. Applications cannot be accepted until the schedule is announced in the publications referred to and cannot be accepted after the closing date as announced.

3. The oral examination will be conducted under the direct supervision of the Board. It will be given by members of the Board of Internal Medicine with the assistance of such Guest Examiners as may be selected. Oral examinations are conducted at the bedside of each of two patients previously assigned to each candidate. Forty-five minutes will be allowed for the examination of each of the patients before the candidate is examined orally. Candidates will be expected to present in a concise, orderly fashion pertinent facts in history and diagnosis. Demonstration of important physical findings will be requested by the examiner. During the oral examination, questions will be asked concerning diagnostic and therapeutic procedures related to the problems under discussion and to any other aspects of Internal Medicine. Conciseness and clarity of statements as well as evidence of clinical maturity will be searched for, in addition to factual knowledge. Furthermore, the candidate should be prepared to demonstrate his ability to interpret objective demonstrations of roentgenologic, pathologic, hematologic, electrocardiographic and other abnormalities.

AMERICAN BOARD OF NEUROLOGICAL SURGERY

A. EARL WALKER, Chairman, Baltimore
EDGAR F. FINCHER, Vice-Chairman, Atlanta, Ga.
GEORGE S. BAKER, Rochester, Minn.
E. JEFFERSON BROWDER, Brooklyn, N. Y.
WILLIAM V. CONE, Montreal, Canada
DEAN H. ECHOLS, New Orleans
FRANC INGRAHAM, Boston
EDGAR A. KAHN, Ann Arbor, Mich.
FRANK MAYFIELD, Cincinnati
WILLIAM T. PEYTON, Minneapolis
JOHN RAAF, Portland, Ore.
LEONARD T. FURLOW, Secretary-Treasurer, 600 S. Kingshighway, St. Louis 10, Mo.

GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession satisfactory to the board of directors.

2. It shall be discretionary with the board to accept for examination candidates who have been in practice more than six years but whose formal training fails to meet the full requirements.

3. Properly qualified candidates who are permanent residents in and citizens of other countries and are legally qualified to practice medicine there, and who have received their training in neurological surgery in the United States of America or Canada may apply for certification by the American Board of Neurological Surgery.

4. A special certificate may be issued to foreign (not United States of America or Canadian citizens) candidates who have received their training in neurological surgery in the United States of America or Canada and who are returning to their own country at the end of their training period, upon passing successfully the regular examinations of this board, without completion of the requirement of two years in the practice of neurological surgery. This special certificate shall be appropriately identified to distinguish it from the regular certificate of this board.

PRELIMINARY PROFESSIONAL STANDING

1. Graduation from a medical school that is acceptable to the American Board of Neurological Surgery.

2. Completion of a surgical internship of not less than one year in a hospital acceptable to the board, or its equivalent in the opinion of the board. (A one year rotating internship does not satisfy this requirement.)

SPECIAL TRAINING

A period of graduate study of not less than four years beyond the year of general surgical training in an approved hospital, or in a recognized graduate school of medicine acceptable to the American Board of Neurological Surgery. Of this training period, at least 30 months must be devoted to clinical neurological surgery. The training in clinical neurological surgery must be progressive and not obtained during repeated short periods in a number of institutions. It is preferable that at least two years of this training be had in one institution, and the board will not ordinarily approve periods of training in clinical neurological surgery of less than one year.

Furthermore the candidate must prepare himself to pass a board examination in general surgery, organic neurology, neuropathology, neuro-anatomy, neuro-physiology, neuro-ophthalmology, and neuro-radiology.

An additional period of not less than two years of satisfactory independent practice of neurological surgery.

The above represent only the minimum requirements of eligibility for examination for certification by the board.

APPLICATIONS

An application on the official application blank in order to be considered at any meeting, must be in the hands of the secretary-treasurer of the board not less than six months before the date of such meeting.

PAYMENT OF FEES

The fee for certification shall be $100.

The candidate for examination on filing his application shall accompany it with an application fee of $25. When notified by the secretary-treasurer that he is eligible for examination he shall send the examination fee of $75 to the secretary-treasurer at least two weeks before the date of the examination.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

F. BAYARD CARTER, President, Durham, N. C.
ROBERT A. KIMBROUGH JR., Vice-President, Philadelphia
HERBERT E. SCHMITZ, Vice-President, Chicago
WALTER T. DANNREUTHER, New York
DANIEL G. MORTON, Los Angeles
JOHN L. PARKS, Washington, D. C.
CONRAD G. COLLINS, New Orleans
R. GORDON DOUGLAS, New York
CARL P. HUBER, Indianapolis
CURTIS J. LUND, Rochester, N. Y.
ROBERT L. FAULKNER, Secretary-Treasurer,
2105 Adelbert Rd., Cleveland 6, Ohio
LAWRENCE M. RANDALL, Assistant Secretary,
Rochester, Minn.

REQUIREMENTS

Each applicant, before he may become eligible to apply for examination, must establish the following facts:

1. The possession of the degree of Doctor of Medicine from an institution of learning approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. That he is a physician of high ethical and professional standing duly licensed to practice medicine in the United States or Canada and is a member of a County or District Medical Society.

3. The completion of at least one year of intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association. The Board

accepts the fifth or "intern" medical year required by some schools in lieu of the usual fifth or intern year of clinical training following graduation.

4. The completion of seven years of training and practice after the first intern year to include at least three years of residency training in clinical obstetrics-gynecology in approved institutions. Approved preceptorship training may be substituted in part for residency training.

5. Following completion of acceptable training, two years of post-training practice, limited to the specialty, are required before application for examination can be made. Post-training practice may include practice within the specialty as an assistant or associate or independent practice. Periods of residency in obstetrics-gynecology in excess of the required three years will not be accepted as a substitute for any part of the two required years of post-training practice except in the cases of men advancing from the residency training into and planning to remain in full time faculty positions in medical schools and their affiliated hospitals.

6. That he is limiting his practice to obstetrics and/or gynecology and intends to continue to do so, except for possible military duty.

7. The Board conformed with the general acceleration in programs in medical education in that it will accept a period of nine "accelerated" months as an academic year in satisfying our requirements for each of three years of residency training. Such allowances can be made only for services during the war-time period of the official "accelerated program" and are not made for services before 1943 or after the discontinuance of this acceleration in 1946.

8. Applicants who have been certified by one of the other American specialty examining boards will not be eligible for certification by this Board until they have relinquished the certificate previously conferred, except upon special action to the contrary taken by the American Board of Obstetrics and Gynecology.

9. The Board has ruled that physicians who accept male patients in their private or other practice, for operative or other care, cannot be regarded as specialists in obstetrics and gynecology, except by special ruling when this is related to active military duty.

10. This Board deprecates engagement in fields of practice other than that in which candidates profess to be specialists. The sole exception to this provision is that it is permissible for candidates and diplomates of the American Board of Obstetrics and Gynecology to participate in emergency care.

11. This Board will not accept applicants for examination who are not full citizens of the United States or of Canada. Foreign born applicants must have been certified by either the National Board of Medical Examiners or licensed to practice medicine in the United States or Canada by a State or Provincial Board of Licensure. Notarized statements, not original citizenship papers, must be furnished when the application is filed attesting to the fact of full citizenship in the United States or Canada, if the applicant is foreign born. Further, there will be required a probationary period of at least three (3) years from the date of licensure in the practice of medicine in these countries before such a candidate may be admitted · examination.

SPECIAL CREDITS AND RULINGS

1. Physicians otherwise qualified, who are graduated before January 1, 1939, and whose required training was in obstetrics or gynecology alone, and who have confined their practice to obstetrics or gynecology for at least five (5) years immediately prior to application may be accepted for examination as candidates for certification in either obstetrics or gynecology. In all other respects requirements for eligibility remain the same as for those physicians graduated since 1939. At least a fundamental knowledge of both obstetrics and gynecology is essential regardless of whether a candidate's practice is limited to one or the other branch.

2. Basic science training should emphasize the relation of anatomy, pathology, physiology, biochemistry, and bacteriology, to the application of surgical principles which are fundamental in all branches of surgery. More especially for this specialty there should be training in infertility, endocrinology, oncology, irradiation therapy, electrotherapy, psychosomatic medicine and other nonoperative methods of diagnosis and treatment. In addition, the candidate must understand and be trained in the care of emergencies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, protein and nitrogen balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, etc.

3. After July 1, 1958, this Board will not allow credit within the three years required training period for separately organized basic science courses which remove the candidate from clinical training in obstetrics and/or gynecology.

4. Training in abdominal surgery, in addition to the required three (3) years of training in clinical obstetrics and gynecology, is desirable and may be included in the total minimal seven (7) years required after the intern year.

5. Applicants on service in obstetrics-gynecology under orders in hospitals of the Army, Navy, Air Force and Public Health Service will receive residency training credit if such hospitals are officially approved for training in this specialty

When the hospital is not approved, preceptorship training credit may be allowed if the service is supervised by a Diplomate of this Board or an otherwise qualified obstetrician and gynecologist. If such training credit is desired, candidates must comply with the regulation governing preceptorships. In addition, the Medical Officers Professional Training Record should be completed and attested while in military service.

Credit toward the required two years of post-training practice, limited to this specialty, will not be allowed for service in the Armed Forces except in the case of regular medical officers who have completed the training requirements.

APPLICATION AND FEES

Application must be made on a special blank which will b furnished by the Secretary's Office and must be forwarded wit the other required credentials and the application fee to th Secretary's Office not later than September 1, of each year.

All candidates must comply with Board regulations in effec for the year in which the examination is taken, regardless when the original application was filed.

Candidates applying for admission to the examinations f certification are required to submit with their application, a unbound typewritten list on 8½ by 11 paper of all patien admitted to the hospitals where they practice, for the ye preceding their application or the year prior to their reque for reopening of their application, with the age, parity, diagnos pathological diagnosis, nature of treatment, and end result.

The list should be certified by the hospital librarian, a ministrator or superintendent.

The application fee is $25.00 and is not returnable

The examination fee is $100.00 and is payable when t candidate is notified of acceptance for examination This is not returnable after the candidate has been officially cepted by the Credentials Committee and notified to rep for examination.

EXAMINATIONS

Part I examinations are scheduled annually for early in January. Arrangements will be made for candidates to report in any convenient city where there may be a Diplomate of this Board to conduct or to supervise the written examination which will be sent out from the Board's office under sealed cover

Special arrangement will be made through senior officers for conducting the written portion of the Part I examination for men in military service. Such candidates are requested to keep the Secretary's office informed at all times of changes in their mailing addresses.

All applicants accepted for examination will be required to obtain a passing grade in both the written examination and a review of case reports (Part I), before becoming eligible for the oral-clinical and pathology examinations (Part II). The passing grade for the written examination and case reports is 75 per cent. A candidate whose grade in either or both falls below 75 per cent is conditioned. Reexamination for the removal of conditions in Part I may be taken after one year but within three years after the first failure, without payment of an additional fee.

Candidates who successfully complete the Part I examination proceed automatically to the Part II examination held later in the year.

Part I

Examination consists of:

1. A comprehensive written examination, conducted annually, luding questions on both obstetrics and gynecology and ated basic sciences. The written examination will be limited a maximum period of three hours.

2. *The evaluation of twenty (20) important obstetrical and* necological case reports in condensed form. Five (5) of the enty (20) *cases may concern major illnesses not necessarily* erative. These reports must include a variety of material ther than a number of reports of one type. Case reports from e's residency service shall not be more than five (5) in mber.

CASE REPORTS

In the case of candidates applying for unilateral certifican, case reports must pertain to the branch for which application is made.

Men holding full-time medical school faculty appointments ay submit the remainder of their case records from this fullme, non-private practice, but post-training service. The candate should prepare and maintain in his possession a carbon py of his case records in case of possible loss in shipping.

Evidence of adequate follow-up examination pertinent to ach individual case must be submitted.

The candidate should *submit separate* verified *index* lists, n duplicate, for each individual hospital at which *operations* ere performed. All of these must be formally signed by *the* esponsible hospital official (preferably the hospital superinndent), attesting in each instance that the candidate was he operator.

Part II

The oral-clinical and pathology examinations given all canlidates are conducted by the entire Board and the associate xaminers. Advance announcements of examination dates and lace will be made in medical journals throughout the country.

Examination consists of:

1. Oral examination before three or more examiners. An ndeavor is made to adapt the details of the oral examination o each candidate's experience and practice. The examination s particularly directed to ascertain his familiarity with recent bstetrical and gynecological literature, the related basic sciences, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology.

2. Pathology examination. The candidate is expected to identify and to discuss pathologic specimens and microscopic sections.

Examiners report orally upon each *candidate to the assembled* Board, after which the results of *their investigations* are considered jointly by the entire Board and associate examiners. After a general consideration of the details of the candidate's oral and pathology examinations, including a review of his capability and general adaptability, the candidate is passed or failed by the entire Board of Directors.

The final action of the Board is based upon the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examination.

GRADUATE TRAINING RESIDENCIES

This Board, through the Council on Medical Education and Hospitals of the American Medical Association, has approved institutions providing acceptable residencies in obstetrics and gynecology.

The American Board of Obstetrics and Gynecology has established the following requirements for its approval of a residency in a hospital department or service:

1. It is most desirable that the Chief of Service of the Department be certified by the Board, in the interests of the proper teaching of the specialty of obstetrics and gynecology. In lieu of such certification the Board will approve of individuals of recognized high professional *standing* in the specialty. At least one additional *senior member of the staff* should be similarly qualified.

2. Exceptions to the foregoing, in respect to the certified status of Chiefs of Service and others as outlined above, can be made by assent of the Committee on Residency Training, for adequate and justifiable reasons. As examples of the latter, the degree of F.A.C.S. in obstetrics-gynecology may be accepted in lieu of one of the two required certifications if the general reputation of the person concerned is known to the Committee as national or sectional in scope, or a professorial rank without certification might be acceptable.

3. In instances where the services of obstetrics-gynecology are not combined but are separate in any given hospital, the Chief of each such service seeking approval and at least one of his subordinates must be certified or otherwise qualified as outlined above. If obstetrics and gynecology are not combined in one department, approval can be granted only if arrangements are made for some degree of rotation of residents between both services, provided both services are separately approved.

4. If gynecology is classified in the given hospital as a subdivision or subservice of general surgery, approval cannot be granted for residency training in gynecology. Exceptions have been made if the subdivision of Gynecology is headed and staffed by a Chief and at least one other certified by this Board or otherwise qualified as specialists in obstetrics-gynecology, as specified above, thus ensuring an acceptable educational program in obstetrics-gynecology.

5. Departments holding official approvals for residency training are cautioned that their totals of residents appointed must be kept to the number specified in the American Medical Association–American Board approval notification. Dilution of training facilities by unauthorized appointment of residents in excess of these numbers may be cause for reinspection and changes in approval status of such hospitals and their special services.

6. For further details of requirements and qualifications for approval for residency training, hospital officials should refer to the latest special issues of THE JOURNAL of the American Medical Association as they appear during each year, dealing with these subjects, or should apply to the Council on Medical Education and Hospitals of the American Medical Association for bulletins entitled Essentials of Approved Residencies and Fellowships.

7. Application for residency approval must be made in triplicate on special forms provided for this purpose. These forms may be obtained from the Secretary of the Council on Medical Education and Hospitals of the American Medical Association. All statements amplifying an application should also be made in triplicate. The hospital should keep a duplicate of all papers.

8. The formal application, with all papers, for residency training approval should be submitted primarily to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois. Action is taken jointly by the Council and this Board after survey by the Council.

9. Approvals are granted according to adequacy of the training program and teaching facilities of various institutions on the following several bases: (a) one-year approval in obstetrics and gynecology (combined) or one-year approval in obstetrics and/or in gynecology (separate), correlated basic science instruction being an essential part of the first year; (b) two-year approval in obstetrics and gynecology (combined) or two-year approval in obstetrics and/or in gynecology (separate), provided there is opportunity in the latter instances for some degree of rotation between the two services as well as laboratory instruction in basic sciences; (c) three-year approval in obstetrics and gynecology (combined) or in obstetrics or in gynecology, provided there is opportunity for one to one and one-half years' service in the branch of the specialty opposite to that in which the candidate holds appointment, as well as laboratory instruction in the basic sciences of both branches.

Exchange residencies within the specialty between approved institutions are acceptable and to be encouraged. Many authorities believe that training in more than one institution is broadening to the candidate. "Farming out" to unapproved institutions or services is not acceptable unless the work of such services is directly and carefully supervised by the Chiefs of the service in the approved hospital under which the man is actively appointed and working. This should be attested by such Chiefs.

Exchange residencies into other specialties cannot be permitted to subtract from the minimal required *three* (3) years of training divided between obstetrics-gynecology.

Two (2) years of post-training practice limited to the specialty is necessary before a candidate may apply for examination.

This Board has no objection to residency services being arranged by hospitals for periods longer than three (3) years, unless this dilutes the candidate's clinical training opportunities too much during the first three (3) years. However, the Board does not accept a fourth year, or more, of residency training as a substitute for any part of the required two (2) years of post-training practice.

The importance of post-training practice in the specialty is emphasized as an opportunity for maturing of the candidate and for colleague appraisal of a man's ability when working on his own responsibility in his chosen community.

Exception to this ruling may be made for men advancing from their training into and planning to remain in full-time teaching positions. These men then must complete at least two (2) years in such positions. Consequently the only institutions in which men may work as fourth and fifth-year residents and obtain credit for this time as "post-training practice" are those directly affiliated with approved schools of medicine as teaching hospitals for undergraduate instruction. These "full-time" men must hold faculty appointments, must have teaching duties with undergraduate students, must be given independent authority more than that of residents, and must make a declaration of intention to remain in full-time teaching work.

10. Any physician formally obligating himself to serve a residency in a Council on Medical Education and Hospitals of the American Medical Association–American Board of Obstetrics and Gynecology approved hospital and thereby eliminating other possible candidates from the position, who breaks his contract without justifiable cause, either before beginning his service or during his period of service, except by mutual consent and agreement between the candidate and the hospital, may be barred from the examinations for certification at the discretion of the Board.

11. It should be recalled by all concerned that credits for graduate training may be obtainable in certain instances for residency or assistantship service in hospitals not officially approved for residency training. Each such case must be individually considered, and credits will be largely dependent upon the teaching qualifications of those in charge of the service, and the clinical facilities of the hospital in question.

PRECEPTORSHIP TRAINING

After July 1, 1958, the initiation of Preceptorship Training must be preceded by two (2) years of formal training in an institution approved for residencies in obstetrics and/or gynecology. Candidates who propose Preceptorship Training must notify the Secretary of the Board of such intent and request an application form. When this has been completed, signed by the Preceptor and Preceptee and returned to the Secretary, it will be submitted (as has long been true of Residency Training Programs) to the Residency Training Committee of the Board for their decision.

If the program is approved the Preceptor must supervise closely the candidate's work and keep an informative record of the candidate's performance. The Preceptor and the Preceptee shall report in writing to the Secretary of the Board at the end of each six months of Preceptorship, outlining the progress of the training program. This information will be placed in the candidate's application for admission to examination in order that it may be evaluated by the Credentials Committee.

As a general rule each year of Preceptor Training will receive a six month's credit toward the total of three years of training necessary for admission to examination. As is the case with candidates whose training has been entirely by formal residency, each application will be evaluated finally by the Credentials Committee.

An acceptable Preceptor preferably shall be one certified by the American Board of Obstetrics and Gynecology and must have been certified for a minimum of five years. Fellowship in the American College of Surgeons or long experience and established reputation as an [illegible] out either of the above qualificati

Preceptor and Preceptee must work in a hospital approved by the Joint Commission on Accreditation of Hospitals.

The post-training practice requirement cannot be carried on concurrently with Preceptorship Training.

AMERICAN BOARD OF OPHTHALMOLOGY

F. Bruce Fralick, Chairman, Ann Arbor, Mich.
Gordon M. Bruce, Vice-Chairman, New York
Merrill J. King, Secretary-Treasurer, Rockland, Maine
Francis H. Adler, Philadelphia
James H. Allen, New Orleans
Alson E. Braley, Iowa City
Paul A. Chandler, Boston
Michael J. Hogan, San Francisco
Harold H. Joy, Syracuse, N. Y.
John S. McGavic, Bryn Mawr, Pa.
C. Wilbur Rucker, Rochester, Minn.
Kenneth C. Swan, Portland, Ore.
Miss Lea M. Stelzer, Registrar, 56 Ivie Rd.,
Cape Cottage, Maine

PREREQUISITES

1. High ethical and professional standing.

2. Full citizenship in the country where the candidate practices. (Limited to countries of North and South America, their possessions and territories, and the Philippine Republic.)

3. A degree from a medical school of high standing, satisfactory to the board and approved by the Council on Medical Education and Hospitals of the American Medical Association. An applicant whose training has been received outside of the United States and Canada must present credentials satisfactory to the board and is required to have the certificate of the National Board of Medical Examiners if he has been in practice less than 10 years.

4. Completion of an internship of not less than one year in a hospital approved by the same Council.

5. Completion, by the time of the written qualifying test, of not less than 36 months (a total of 60 months is required of candidates practicing both ophthalmology and otolaryngology) of combined study, training, and practice of ophthalmology in approved medical schools, hospitals, clinics, dispensaries, laboratories, preceptorships, and private practice.

6. Effective January 1, 1957:

(a) Licensure in the state, province, or country where the candidate practices.

(b) Individuals who have completed three years of formal ophthalmological training (residency and basic science courses) will be eligible to apply for the written qualifying test after completion of one year of practice or of one year of institutional work. All other individuals (with less formal training) will be eligible to apply for the written test after 60 months in ophthalmology or 72 months of combined ophthalmology and otolaryngology. A basic course is recognized as equivalent in time to residency training.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

1. Application forms must be filled out completely and accurately. Letters of endorsement, together with any other required credentials, must be sent to the secretary's office before the deadline date.
2. Fee of $100 remitted with application.
3. A list of papers or books published.
4. Written qualifying test.
5. Practical examination.
6. Special review of ophthalmic surgery.
7. Licensure in the State, Province or country where the candidate practices.

FEES

For original written test, $100.00, payable with application.

For original clinical examination, $50.00, payable on successful completion of the written.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY

orge J. Garceau, President, Indianapolis
arles J. Frankel, Vice-President, Charlottesville, Va.
ther Cleveland, New York
win F. Cave, Boston
lliam H. Bickel, Rochester, Minn.
Benjamin Fowler, Nashville, Tenn.
orge W. N. Eggers, Galveston, Texas
Vernon Luck, Los Angeles
m W. Banks, Secretary-Treasurer, 116 S. Michigan Ave.,
Chicago 3, Ill.

GENERAL ELIGIBILITY REQUIREMENTS

1. Satisfactory moral and ethical standing in the profession.

2. Graduation with a degree of doctor of medicine from a dical school of the United States or Canada recognized by Council on Medical Education and Hospitals of the Amern Medical Association, or graduation from a foreign school the approved list of the aforementioned Council.

3. Completion of an internship of not less than one year a hospital approved at that time by the Council on Medical lucation and Hospitals of the American Medical Association , if trained in foreign countries, in institutions considered tisfactory by the American Board of Orthopaedic Surgery.

4. Completion of one year of resident training in general gery in a hospital approved by the Council on Medical Edution and Hospitals of the American Medical Association or bstitute training in general surgery considered satisfactory by e American Board of Orthopaedic Surgery. The minimum one year of training in general surgery is in addition to e minimum of one year of internship. This requirement may fulfilled by substituting a second year of internship, by time ent in research, by time spent on a service in which there an overlap of interest with orthopaedic surgery, by a fourth ar of approved orthopaedic resident training, or by surgical ork in private or military life.

5. Completion of formal requirements for part 1 or part 2 aminations. These formal requirements can be satisfied only y resident orthopaedic training.

Applicants may not be admitted to examinations, or be cerfied, on the basis of extensive specialized practice and/or aching appointments and/or many short unapproved courses.

6. Restriction of practice to orthopaedic surgery.

REQUIREMENTS FOR PART 1 EXAMINATIONS

1. Completion of and compliance with aforementioned genral eligibility requirements.

2. Citizenship in the United States or Canada, or possession f citizenship papers showing intent to become a full citizen.

3. Following completion of a year of internship, satisfactory ompletion of a minimum of one year of general surgical traing, or its substitute, plus (a) two years of approved training n orthopaedic surgery under a program of resident training.

4. Evidence of competence in training.

5. Approval for examination by the committee on eligibility of the American Board of Orthopaedic Surgery.

REQUIREMENTS FOR PART 2 EXAMINATIONS

1. Successful completion of part 1 examinations.

2. Full citizenship in the United States or Canada.

3. License to practice in the United States or Canada.

4. Satisfactory completion of a minimum of three years of approved resident training in orthopaedic surgery, plus a minimum of two subsequent years of practice period.

5. Evidence of competence in practice.

6. Approval for examination by the committee on eligibility of the American Board of Orthopaedic Surgery.

APPLICATION AND EXAMINATION FEE SCHEDULE

1. Application for part 1, fee $15, not returnable.

2. Examination, part 1, fee $35, payable only if approved for examination. Approved candidates failing to appear for scheduled examinations forfeit fees.

3. Application for part 2, fee $15, not returnable.

4. Examination, part 2, fee $50, payable only if approved for examination. Approved candidates failing to appear for scheduled examinations forfeit fees.

APPLICATIONS

1. Applications for part 1 examinations must be received in the office of the secretary of the board before November 30 of the year preceding the examinations.

2. Applications for part 2 examinations must be received in the office of the secretary of the board before August 15 of the year preceding the examinations.

3. Notices of acceptance for admission to the part 1 examinations are mailed to eligible candidates during the month of February in the year of the examinations.

4. Notices of acceptance for admission to part 2 examinations are mailed to eligible candidates during the month of November in the year preceding the examinations.

5. Questions of eligibility for examinations are decided by the committee on eligibility of the board. This committee meets twice yearly. The secretary is not empowered to rule on questions of eligibility.

6. The life of an application is three years. After this time a new application and application fee must be submitted.

EXAMINATIONS

1. Part 1 examinations are held once yearly, usually in April or May, in various centers in the United States.

2. Part 2 examinations are held once yearly, usually in one center, immediately preceding the meeting of the American Academy of Orthopaedic Surgeons.

3. The locations and dates of coming examinations are announced in The Journal of the American Medical Association and the *Journal of Bone and Joint Surgery.*

CERTIFICATION

1. Applicants who successfully pass part 1 examinations will receive no certificate but will be notified by letter by the secretary.

2. Applicants who successfully pass part 2 examinations receive a certificate of the board, which states that they have been found qualified to practice the specialty of orthopaedic surgery in those fields in which they have been trained and examined.

3. Candidates obtaining certification without training and examination in children's orthopaedic surgery may subsequently add certification in children's orthopaedic surgery by completing a minimum of one year of approved resident orthopaedic training in children's orthopaedic surgery and successfully passing examination in that field. A practice period of one year is required following completion of resident training, prior to examination for additional certification.

APPROVED RESIDENCIES

1. In the United States, resident training must be taken in institutions approved for resident training in orthopaedic surgery by the Council on Medical Education and Hospitals of the American Medical Association. All approved institutions are listed yearly in the Internship and Residency Number of The Journal. Lists may be obtained from the American Medical Association and are not obtainable from the board.

2. The integral parts of approved residencies are designated in lists by the following symbols: A—adult orthopaedic surgery; C—children's orthopaedic surgery; F—fracture surgery; and S—basic science training. Approved length of training in institutions is also designated.

3. Candidates electing an additional year of training in adult orthopaedic surgery and fracture surgery in lieu of a year in children's orthopaedic surgery may satisfy requirements by continuing their training beyond the designated approved length of time in institutions appoved for adult orthopaedic surgery or adult orthopaedic surgery and fractures.

4. Credit for resident training is not retroactive. Candidates must receive resident training in institutions during periods that such institutions are on the approved list. If candidates are in training at institutions at the time that such institutions become approved, resident training credit may be granted from the start of the training period provided that the program is judged to have been satisfactory.

5. Candidates in resident training, or possessing signed contracts for future resident training in institutions which become disapproved, either in whole or part, receive resident training credit for the entire period during which their contracts are in force.

6. The term "fellow" is considered synonymous with "resident" when the position occupied and the work performed is equal in all functions. Fellowships in institutions having residents, in which training and responsibilities are not equal, are not credited as resident training.

7. Institutions approved for resident training in orthopaedic surgery by the Council on Medical Education and Hospitals of the American Medical Association may, with prior acceptance by the American Board of Orthopaedic Surgery and notification to the Council, utilize the training facilities of institutions not individually approved for resident training by the aforementioned Council, provided that: (a) the training supplements services in the same categories in which the institution responsible for training is approved by the Council, (b) the resident spends at least half of the minimum required time in each category of training in institutions approved by the Council.

8. Foreign residencies must satisfy the American Board of Orthopaedic Surgery.

9. Application for approval of the training facilities of any institution must be made to the Council on Medical Education and Hospitals of the American Medical Association, and inspection of such facilities is made by representatives of the Council. Final approval is a joint function of the Council and the American Board of Orthopaedic Surgery.

REQUIREMENTS OF RESIDENT ORTHOPAEDIC TRAINING

1. Institutions approved for full three year programs including all parts of the training requirements may integrate all parts so that they are given concurrently.

2. Institutions now approved for less than three years of orthopaedic resident training should arrange with other approved institutions to provide complete three year programs for all residents.

3. The minimum requirements of resident orthopaedic training are as follows: (a) one year of training in adult orthopaedic surgery, (b) six months of training in the basic sciences, (c) six months of training in fracture surgery, and (d) one year of training in children's orthopaedic surgery or, if elected, an additional year of training in adult orthopaedic surgery and fracture training in place of training in children's orthopaedic surgery.

4. Candidates who elect an additional year of training in adult orthopaedic and fracture surgery instead of a year in children's orthopaedic surgery may satisfy the requirements by taking the additional year of training in adult orthopaedic surgery or six months of adult orthopaedic surgery and six months of fracture surgery, but may not take the entire year of training in fracture surgery.

5. Training in adult and children's orthopaedic surgery must include observation and firsthand experience in diagnosis treatmet, operative and postoperative care of orthopaedic problems.

6. Training in fracture surgery must include observation and firsthand experience in diagnosis, treatment, operative and postoperative care of recent and old fractures.

7. Training in the basic sciences must instill a sound knowledge of anatomy, pathology, physiology, bacteriology, and biochemistry as these basic sciences apply to orthopaedic surgery.

8. Candidates may complete the training requirements by training in several approved institutions provided that all the aforementioned minimum requirements are satisfied on approved services.

9. No training period of less than six consecutive months in one institution may be credited toward resident training requirements, except a few short courses on the board's approved list and recognized supplementary services of approved institutions.

10. Candidates in resident training may not engage in private practice.

11. Candidates in resident orthopaedic training must receive their training in institutions and may not receive credit for time spent assisting in private office practice.

SEQUENCE OF EXAMINATIONS AND PRACTICE REQUIREMENTS

1. No person may take part 2 examinations until after successful completion of part 1 examinations.

2. Successful completion of part 1 examinations in no way obligates the board to declare a candidate eligible for part 2 examinations.

3. Regardless of how extensive or prolonged a practice a candidate may have had prior to completing the training requirements, such time may not be credited toward practice requirements. All practice requirements must be satisfied subsequent to completion of training requirements

4. Candidates may not be admitted to examinations on the basis of prolonged practice but must qualify on the basis of formal training.

PRACTICE REQUIREMENTS

1. Candidates must maintain high ethical and professional standards.

2. Candidates must strive to increase their scientific knowledge.

3. Candidates must limit their practice to orthopaedic surgery.

4. Candidates who have had no approved training in children's orthopaedic surgery must confine their practice to fracture and adult orthopaedic surgery.

5. Candidates trained in resident orthopaedic training are required to complete a minimum of two years of orthopaedic practice subsequent to the completion of their formal training before becoming eligible for part 2 examinations

6. Candidates in private or institutional practice must spend a minimum of 14 months in one locality immediately prior to application in order that practice may be properly evaluated

7. Candidates employed full time in institutions may satisfy practice requirements by serving a minimum of two years, but minimum requirements may not be satisfied by mixing full-time institutional work with preceding or subsequent time in private practice.

METHOD OF EXAMINATION

1. Part 1 examinations consist of a written examination and oral examinations. Material covered includes fundamental surgical principles, elementary fracture and orthopaedic procedures, history-taking, and physical examinations as well as those parts of anatomy, pathology, physiology, and biochemistry related to orthopaedic surgery. The oral examinations consist of five parts: (a) anatomy, (b) pathology, (c) physiology and biochemistry, (d) surgery, and (e) fractures and orthopaedic surgery.

2. Part 2 examinations consist of a written examination and oral examinations Material covered includes advanced work in all phases of orthopaedic surgery. The oral examinations consist of five parts: (a) anatomy, (b) pathology, (c) children's orthopaedic surgery, (d) fractures, and (e) adult orthopaedic surgery.

3. Candidates who have not had approved training in children's orthopaedic surgery will not be examined in that branch of orthopaedic surgery.

4. Candidates are notified by letter as to whether they passed or failed in the examinations. No information regarding results is available until such letters are mailed.

5. Results of integral parts of examinations are not available to either candidates or diplomates of the board.

6. Candidates who have passed part 1 examinations are required to take part 2 examinations within a 10 year subsequent period. If there is a lapse of more than 10 years, candidates must repeat part 1 examinations and must then become eligible by the requirements then in force.

MILITARY SERVICE

1. Medical officers who have elected service in the military forces as their life careers compete for certification on the same basis as do physicians in civilian practice.

2. Physicians who served for a minimum of one year in the military forces during the war years, between Jan. 1, 1941, and July 1, 1946, are granted a bonus of one year of practice credit, provided that the same time is not used for resident training credit.

3. Applicants who served in military hospitals whose service judged by the board to have been equal to that of approved sident orthopaedic training may be granted a maximum credit one year of resident orthopaedic training. Applicants request- ıg such credit must submit completed "Professional Training ecords."

4. No applicant may be granted more than one year of resi- ent training credit and one year of practice credit for military ervice during the war years.

5. Medical officers assigned to civilian institutions on the pproved list for resident orthopaedic training receive the same redit as do civilian candidates.

6. Medical officers who have elected service in the military orces as their life careers must satisfy the practice requirements y military assignments in which their duties are limited to the ractice of orthopaedic surgery.

RECORDS OF SURGICAL CASES AND INSPECTIONS

1. Records of a specified number of consecutive surgical cases nay be requested by the board in order to evaluate properly he work of an applicant.

2. A representative of the board may visit a community in rder to evaluate properly the work of an applicant.

George F. Reed, Boston
LeRoy A. Schall, Boston
Harry P. Schenck, Philadelphia
O. E. Van Alyea, Chicago
Dean M. Lierle, Secretary-Treasurer, University Hospitals,
Iowa City, Iowa

GENERAL REQUIREMENTS

The following general qualifications of candidates for examination are required by the board:

1. A candidate must have been a graduate for five years or more of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. A candidate must be of known good moral character and be ethical in his professional relationships.

3. A candidate trained in a foreign country must be able to give proof of medical and graduate training comparable to the requirements of the board.

4. A candidate from the United States or the Dominion of Canada must be a member of the American Medical Association or of the Canadian Medical Association respectively or other such medical societies of equal standing as are recognized by the Council on Medical Education and Hospitals of the American Medical Association.

5. Candidates from foreign countries who have received their training in otolaryngology in the United States and the Dominion of Canada are eligible for examination at the discretion of the American Board of Otolaryngology, provided they meet the general academic requirements of the Board.

SPECIAL REQUIREMENTS

1. A candidate must have had a general internship of at least one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. A candidate must be proficient in the applied basic sciences, fundamental to the intelligent practice of otolaryngology. These include anatomy of the ear, nose, and throat, neck, chest, esophagus and nervous system, gross pathology and histopathology, bacteriology, physiology, didactic otolaryngology and the general fundamentals of surgery. (This requirement may be fulfilled in a residency or fellowship service or in an approved organized post-graduate course.)

3. In addition to the general internship, the required clinical training in otolaryngology may have been acquired in any of the following ways:

(a) A three years' residency or fellowship in otolaryngology approved by the Council on Medical Education and Hospitals of the American Medical Association.

(b) A four years' approved residency or fellowship in otolaryngology and ophthalmology provided one half of the training has been in otolaryngology.

(c) A two years' approved residency or fellowship in otolaryngology or a three years' approved combined residency or fellowship in otolaryngology and ophthalmology, provided two years have been in otolaryngology and have been preceded by at least one year's approved residency training in surgery or medicine, or by an additional year in an approved internship.*

4. In exceptional circumstances certain candidates who do not meet all of the above requirements may be accepted for examination on recommendation of the credentials committee, substantiated by action of the board.

5. At least one year must be spent in private, group, or institutional practice of otolaryngology after the period of special training. This requirement may be waived in cases of candidates from foreign countries who are returning there for the practice of otolaryngology. Should such a candidate pass the examination the certificate of the board will be withheld until the board has been furnished evidence that the candidate has spent one year in the practice of otolaryngology. (When the requirement of an additional year referred to in No. 5 may impose handicaps as to rating, in the Military or Veterans Administration Services. the candidate may be considered under No. 4 above.)

6. A candidate may be qualified for examination, at the discretion of the American Board of Otolaryngology, if in addition to the General Requirements and Special Requirements, No. 1 and 2, he has limited his practice to otolaryngology for seven years in association with a hospital staff approved by the Council on Medical Education and Hospitals of the American Medical Association.

7. A physician who limits himself exclusively to the practice of peroral endoscopy may be granted limited certification in this field by the American Board of Otolaryngology irrespective of certification in any other specialty. Limited certification will be granted provided the candidate has spent not less than one year of training in a hospital approved for endoscopic teaching and has passed successfully examinations in the basic sciences as they pertain to this field, and didactic and clinical examinations covering diseases of the larynx, pharynx, neck, esophagus, stomach, tracheobronchial tree, lungs and mediastinum and certain aspects of cardiovascular disease as they pertain to peroral endoscopy. A limited certificate by the American Board of Otolaryngology will not be issued to physicians who have been certified in a specialty that employs peroral endoscopy in diagnosis and/or treatment because his major interest is in that specialty, not in endoscopy.

All candidates must comply with current board regulations, regardless of the time of filing application.

APPLICATION AND FEES

1. Application must be made in duplicate on special blanks procured from the secretary. The completed application blanks must be returned to the secretary, together with the other required credentials, at least 120 days in advance of the examination at which the candidate desires to appear.

---

*See Standards for Residencies in Otolaryngology published by the American Medi[illegible]Association.

2. The applications must be accompanied by two small photographs of the candidate, together with verification of the period of enrollment from the institutions where training in otolaryngology was obtained, and the names of two or more otolaryngologists, preferably diplomates of the board, from the vicinity of the candidate's place of residency, to be used as references.

3. The fee for the examination is $150. Of this sum $75 must accompany the application, of which $50 shall be returned if candidate is not accepted for examination. No application will be acted on until the $75 application fee is received. The remaining $75 of the total examination fee of $150 must be paid to the secretary on notification that the candidate has been accepted.

4. The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expense.

5. The application remains valid for three years. An applicant must appear for examination within this time or forfeit the fee.

6. Candidates whose credentials have been found satisfactory and who meet the requirements of the board will be notified 90 days prior to the date of examination. The number of candidates who can be admitted to any one examination is limited. Due to a large number of applications on file, delay in assignment for examination may be inevitable. Appointments will be given in the order applications are accepted and on payment of the balance of the examination fee.

7. The board, acting as a committee of the whole, reserves the right to reject an applicant for any reason deemed advisable and without stating the same, and the action of the board shall be final.

EXAMINATION

Examinations will be held at such time and place as the judgment of the board may dictate. Advance notice of examinations will be given in THE JOURNAL of the American Medical Association and the several special journals devoted to otolaryngology. Insofar as is possible these will be held biannually at, or near, the time and place of meeting of the American Medical Association, or special societies, and of the American Academy of Ophthalmology and Otolaryngology. The examinations cover from two to four days.

Scope.—This examination encompasses all phases of otolaryngology and peroral endoscopy, including maxillofacial surgery, and surgery of the neck, excluding the thyroid.

The type of examination is as follows:

1. Clinical, covering the actual handling of patients, including history-taking, physical and functional examinations, the use of laboratory and x-ray findings, and a discussion of differential diagnosis.
2. Didactic, oral examinations covering all phases of otolaryngology.
3. Gross and microscopic pathology.
4. A written examination may be included when the board deems this advisable.

AMERICAN BOARD OF PATHOLOGY

SHIELDS WARREN, President, Boston
WILLIAM B. WARTMAN, Vice-President, Chicago
JOHN J. ANDUJAR, Fort Worth, Texas
ROGER D. BAKER, Durham, N. C.
ISRAEL DAVIDSOHN, Chicago
JAMES W. KERNOHAN, Rochester, Minn.
DOUGLAS A. MACFADYEN, Chicago
ALAN R. MORITZ, Cleveland
JAMES N. PATTERSON, Tampa, Fla.
S. BRANDT ROSE, Philadelphia
JOHN R. SCHENKEN, Omaha
EDWARD B. SMITH, Secretary-Treasurer, Indiana University Medical Center, 1040-1232 W. Michigan St., Indianapolis 7, Ind.

GENERAL REQUIREMENTS

1. Satisfactory moral and ethical standing in the profession.
2. License to practice medicine or a certificate of the National Board of Medical Examiners.
3. The applicant must devote his time primarily and principally to the practice of pathology.

PROFESSIONAL EDUCATION

1. Graduation from a medical school in the United States approved by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from medical schools in other countries acceptable to the board.

SPECIAL TRAINING AND EXPERIENCE

1. The board admits candidates to examinations who are otherwise eligible and who have had either of two following types of training and experience.

(a) After five years, if four of the five years have been in institutions approved by the Council on Medical Education and Hospitals of the American Medical Association or by the board; or

(b) After 11 years if none of the training and experience has been in institutions so approved.

2. The specific requirements for those acceptable after five years are as follows:

(a) Pathological anatomy only.

(1) Four years of supervised study and training in an institution approved for residency training in pathological anatomy by the Council on Medical Education and Hospitals of the American Medical Association or by the board. It is immaterial whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed 12 months of a straight or rotating clinical internship or a fellowship or instructorship in any of the preclinical departments of a university for one of the four years. In addition time, not to exceed 12 months, spent in a department of pathology of an approved school of medicine after the completion of the second year of undergraduate study may be counted for full credit toward the four years.

(2) One additional year, which may be a continuation the preceding or may be independent practice of pathologic anatomy in a hospital approved by the American Medic Association or other institutions acceptable to the board.

(b) Clinical pathology only.

(1) Four years of supervised study and training in an in tution approved for residency training in clinical pathology the Council on Medical Education and Hospitals of the Am can Medical Association or by the board. It is immate whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed 12 months of a straight or rotating clinical internship or a fellowship or instructorship, in any of the preclinical departments of a university, for one of the four years. Candidates holding also a master's or doctor's degree in a special field of clinical pathology (bacteriology, serology, chemistry, parasitology, or hematology) may obtain time credit for not more than 12 to 24 months toward the four years for this work, regardless of whether it was taken before or after the medical degree. The evaluation of time credit will depend on how much of the broad field of clinical pathology was covered in the graduate work.

(2) One additional year, which may be a continuation of the preceding or may be independent practice of clinical pathology in a hospital approved by the American Medical Association or other institutions acceptable to the board.

(c) Pathological anatomy and clinical pathology.

(1) Four years of supervised study and training divided as follows: (a) two years of supervised study and training in pathological anatomy as outlined in the preceding paragraph 2-(a)-(1), (b) two years of supervised study and training in clinical pathology as outlined in the preceding paragraph 2-(b)-(1). Candidates declared eligible before July 1, 1953, may, at their own election, substitute one year (twelve months) of a straight or rotating clinical internship for one year of this special training in clinical pathology. After July 1, 1953, all candidates applying for both pathological anatomy and clinical pathology will be required to have two years of supervised training in clinical pathology.

(2) One additional year, which may be a continuation of the preceding or may be independent practice of both pathological anatomy and clinical pathology in a hospital approved

the American Medical Association or other institutions eptable to the board. After July 1, 1953, candidates who ct to claim credit for one year for a clinical internship must e this fifth year as supervised study and training in clinical thology in institutions approved for residency training in nical pathology by the Council on Medical Education and spitals of the American Medical Association or by the board. ndidates declared eligible after July 1, 1953, who do not e a clinical internship, may, after four years of training as tlined in 2-(1)-(a) and (b), spend the fifth year in independent practice in an institution or laboratory acceptable to e board.

Note: As outlined in the preceding paragraphs, the total e requirements of the board are unchanged after July 1, 53, namely, five years of study or practice after graduation m medical school, with exceptions noted in sections 2-(a)-) and 2-(b)-(1).

3. The specific requirements for those acceptable after 11 ars are as follows: (a) The practice of pathology under cumstances acceptable to the board for a period of not less an 11 years. At the election of the candidates, a period not exceed one year of straight or rotating clinical internship ay be substituted for one of the 11 years. For those candiates in this category who have had some special study and aining in pathologic anatomy or clinical pathology acceptable pervised study and training, only seven years of practice are quired.

CREDIT FOR MILITARY SERVICE

Credit may be allowed for training and experience in patholgy in the federal services during the period July 1, 1940, to ne 30, 1947. This credit for training or experience or both is ven on an individual basis and will depend on the opportunity e applicant has had, as indicated by his or her medical service cord in the specialty of pathology.

After July 1, 1947, credit for those military services will be ven on the same basis as it is in civilian institutions, except at the rule in the preceding paragraph will not apply to serve officers who continue on active duty or are called to tive duty after that date.

PECIAL FIELDS OF PATHOLOGY, CLINICAL CHEMISTRY, CLINICAL MICROBIOLOGY, HEMATOLOGY, AND NEUROPATHOLOGY

(IN FORCE AFTER JULY 1, 1954)

The trustees of the American Board of Pathology have dopted the following requirements for certification in special elds of pathology, effective July 1, 1954.

Candidates who have met all general requirements and have ad special training and experience that is acceptable to the oard in a special field of pathological anatomy or clinical athology may apply to the board for certification in that pecial field. The board, at its discretion, may approve this pplication, and after the candidate has successfully passed a rescribed examination or has fulfilled certain special qualifications (see below, section D), will issue a certificate designating he special field.

A. General Qualifications:

1. Satisfactory moral and ethical standing in the profession.
2. License to practice medicine or a certificate of the National Board of Medical Examiners.
3. The applicant must devote his time primarily and principally to the practice of pathology or the special field of patholgy in which he is requesting certification.

B. Professional Education:

1. Graduation from a medical school in the United States approved by the Council on Medical Education and Hospitals of the American Medical Association or graduation from a medical school in other countries acceptable to the board.

C. Special Training and Experience:

The board admits candidates to examination in special fields of pathology who are otherwise eligible and who have had either of the following types of training:

1. Applicants already holding a certificate of the board in clinical pathology or the combined certificate in pathological anatomy and clinical pathology (for qualification in clinical chemistry, clinical microbiology, and hematology), or in pathological anatomy (for qualification in neuropathology)—two additional years of supervised training in the special field of their choice in institutions approved by the Council on Medical Education and Hospitals of the American Medical Association or by the board.
2. Applicants not holding a certificate in pathological anatomy or clinical pathology—five years of training in the special field of their choice, provided four of the five years have been in institutions approved by the Council on Medical Education and Hospitals of the American Medical Association or by the board. Candidates may, at their own election, substitute not to exceed 12 months of a straight or rotating clinical internship or a fellowship or instructorship in any of the preclinical departments of a university for one of the four years. The fifth year may be a continuation of supervised training or may be independent practice of the particular specialty in a hospital approved by the American Medical Association or in other institutions acceptable to the board.

D. Special Qualifications—Certification Without Examination:

Prior to Jan. 1, 1960, the board at its discretion may certify candidates without examination if the following conditions have been met as of Jan. 1, 1955:

1. That the candidate has been for a period of five years of professorial rank in the special field of his choice and in an approved medical school, or
2. That the candidate has been practicing his specialty for 10 years in a senior position in a hospital having an adequate department in the special field, approved by the Council on Medical Education and Hospitals of the American Medical Association, or in an institution acceptable to the board.

APPLICATION BLANK AND FEE

Application must be made on the special form that may be procured from the secretary and forwarded with other required credentials and the application fee. An application cannot be given consideration by the board unless it is accompanied by the application fee.

The application or examination fee for candidates is $100. If the candidate fails in his examination he will be admitted to a second examination after one year. The applicant must pay an additional fee of $50 before a second examination will be given.

The application fee of $100 has been determined after careful consideration and is based on actual estimates of the expenses of examination and administration. None of the board members receives any compensation for his services except actual expenses incurred.

If the applicant, for any reason, is deemed ineligible for examination by the board, his fee will be returned; however, the application fee is not returnable after the candidate has officially been accepted for examination and notified to report for the examination.

EXAMINATIONS

Written and oral examinations will be held at the discretion of the board at or near the time and place of national medical meetings. If a number of applications from any region of the country are received, an examination in conjunction with a national medical meeting in that section will be arranged so that the financial outlay of the applicant in meeting the examiners will be as small as possible.

The examinations are to be based on the broad principles of pathology with emphasis on diagnosis, interpretation and technique. The applicant may apply for certification in either pathological anatomy or clinical pathology or both.

The examinations in pathological anatomy consist of a written test, an oral examination on gross pathology, and a practical examination in microscopic pathology. The examination in clinical pathology consists of a written test and an oral and practical examination in the six phases of clinical pathology: bacteriology, hematology, clinical chemistry, parasitology, serology, and clinical microscopy.

DEFINITIONS

1. Pathological anatomy is that branch of pathology that deals with the morphological aspects of disease, recognition being given that that definition covers two phases of pathology: (a) the applied phase with special attention to the description and diagnosis of gross and microscopic specimens, (b) the academic phases of teaching and general morphological diagnosis.

2. Clinical pathology is that branch of pathology that deals with bacteriology, immunology, clinical chemistry, parasitology, hematology, endocrinology, clinical microscopy, and the application of the physical and biological sciences to the diagnosis, prognosis, and treatment of disease.

CRITERIA FOR APPROVAL OF INSTITUTIONS FOR TRAINING IN PATHOLOGY

In Sections C-2-a, C-2-b, and C-2-c of the General Requirements, it is stated that candidates must have certain periods of supervised study and training. The American Board of Pathology, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association, certifies hospitals in the United States as satisfactory for this supervised study and training. Lists of these hospitals are published in the Internship and Residency Number of The Journal of the American Medical Association each year. In addition, the American Board of Pathology recognizes certain hospitals outside the United States and certain laboratories not connected with hospitals in the United States. Inquiries concerning these should be directed to the secretary of the board.

The general criteria for approval of hospitals and laboratories are both qualitative and quantitative. On the score of quality, consideration is given to the qualifications of the director of laboratories and in the associates and assistants, the supervision of work of the person in training, the excellence of the educational program, and the exactness and completeness of the laboratory work performed. On the score of quantity, consideration is given to the volume and distribution of laboratory work, both in absolute numbers and in relation to the size of the hospital, to the diversity and completeness of tests performed, to the size and equipment of the laboratory, and to the number of professional and nonprofessional personnel in relation to the volume of work.

In general, the qualitative standards will determine whether or not a hospital or laboratory is approved and the quantitative standards will determine whether the approval is for one, two, three, or four years of credit toward the requirements of the board.

In evaluation of applications the board takes into consideration the following criteria:

1. Director of laboratories or pathologist:

(a) It is required that the responsible head of the laboratory hold the certificate of the American Board of Pathology in the subject for which the hospital is approved, or be eligible for certification, and that he or she spend full time in the hospital. *Full time is not interpreted in terms of hours, but* rather that the director have no obligation outside the one approved hospital except in a university department of pathology in which he and the residents have an opportunity to participate in the educational program;

(b) In special instances, the equivalent of full time by two or more qualified persons will be accepted and one person need not spend the entire working day in the laboratory;

(c) In special instances, two or more hospitals will be approved as a unit with a single full-time director of laboratories if it is apparent that a satisfactory training program can be conducted;

(d) In hospitals with over 350 beds, it is expected that the professional staff, in addition to the pathologist, will include one or more persons with special training and qualifications in the sub-specialties of clinical pathology.

2. Technicians:

There are no absolute criteria, but it is expected that the number of technicians will be proportional to the volume of laboratory work and that, insofar as possible, the technicians will hold the certificate of the Registry of Medical Technologists of the American Society of Clinical Pathologists.

3. Floor space of laboratory:

In general, it is believed that the size of the laboratory should be related to the size of the hospital and the volume of laboratory work. A minimal ratio is 4 square feet of space in the laboratory, including morgue and autopsy room, for each bed in the hospital.

4. Equipment for the laboratory:

The variety and completeness of laboratory tests performed depend on the size of the hospital. In all hospitals there should be facilities for the more common test in clinical pathology, for study of surgical specimens, and for performance of autopsies. In larger hospitals, the variety of tests performed should be larger, and in hospitals with over 500 beds all recognized laboratory procedures should be available for study and treatment of the patients.

5. Autopsy percentage:

No institution with a percentage of less than 15 will be approved, and those institutions with percentages between 15 and 40 will be given special scrutiny.

6. Examination of surgical specimens:

All surgical specimens should be sent to the laboratory for gross examination, and microscopic examinations should be made unless there are general or special reasons not to do so.

7. Indices:

There should be indices according to the names of the patients and the diagnoses of all surgical and autopsy material. Indices of clinical pathology are left to the discretion of the hospital.

8. Museum:

There should be available fixed anatomic and pathological specimens for study by the staff in proportion to the size of the hospital. Properly filed and indexed color photographs may in part be substituted for museum specimens.

9. Library:

A reasonable complete library of modern books and recent unbound and bound journals should be available to the hospital and the more commonly used books and journals should be on hand in the laboratory.

10. Education program:

The work of the person in training should be supervised. Conferences, seminars, journal clubs, and demonstrations should be conducted as frequently as the volume of material and the size of the staff justifies. A clinicopathological conference must be held at least every two weeks.

11. Volume of laboratory work:

(a) As indicated in the following categories, no hospitals with less than 75 autopsies, 1,000 surgical specimens, and 25,000 tests in clinical pathology annually will be approved (Category D), except as outlined in the following paragraphs. It is the belief of the board that less material than this is inadequate for the training of a pathologist.

(b) In the field of clinical pathology, there should be a reasonable diversification of tests, and in each category there should be sufficient absolute volume to provide training and experience. There are no absolute criteria, but special scrutiny will be given to a hospital in which there is not a reasonable diversification and variety.

(c) In the field of pathological anatomy, a deficiency in either autopsies or surgical specimens may be made up by an excess of the other, if the deficiency does not exceed 20% of the minimum required in the ratio of one autopsy to 75 surgical specimens. Thus in a hospital approved for one year in pathological anatomy and clinical pathology, the minimums are 75 autopsies and 1,000 surgical specimens. If a hospital has 2,500 surgical specimens, it is acceptable if there are only 60 autopsies.

If a hospital has met these minimal qualitative and quantitative standards, it will then, on the basis of the following quantitative standards, be approved for one, two, three, or four years of training in pathological anatomy, or clinical pathology, or both, or some special field as shown for the number of residents indicated.

Category A. In both pathological anatomy and clinical pathology for four years (as required of all candidates seeking certification in both fields who are examined after July 1, 1952).

Minimum: 150 autopsies, 1,750 surgical specimens, and 65,000 tests in clinical pathology for four residents. Additional resident for each 50 autopsies or 500 surgical specimens, or 20,000 tests in clinical pathology.

Category B. In both pathological anatomy and clinical pathology for three years. This meets all requirements of the board for supervised training until July 1, 1952. Candidates examined after that date who seek certification in both subjects must take an additional year of supervised training in clinical pathology or pathological anatomy in another hospital that is approved for the deficiency of training required.

Minimum: 125 autopsies, 1,500 surgical specimens, and 0,000 tests in clinical pathology for three residents. Additional esident for each 50 autopsies, 500 surgical specimens, or 0,000 tests in clinical pathology.

Category C. In both pathological anatomy and clinical pathology for two years. Candidates taking two years in these nstitutions must have an additional year (two years after July 1, 1952) in an institution in category A, B, or D.

Minimum: 100 autopsies, 1,250 surgical specimens, and 0,000 tests in clinical pathology for two residents. Additional esident for each 50 autopsies, or 500 surgical specimens or 20,000 tests in clinical pathology.

Category D. In both pathological anatomy and clinical pathology for one year. Candidates taking training in these institutions must have an additional two years (three years after July 1, 1952) in institutions that are approved for the deficiency of training required.

Minimum: 75 autopsies, 1,000 surgical specimens, and 25,000 tests in clinical pathology for one resident. Additional resident for each 50 autopsies, or 500 surgical specimens, or 20,000 tests in clinical pathology.

Category E. In pathological anatomy only, for three or more years. Candidates taking all training in these institutions will not be eligible for certification in clinical pathology unless an additional year (two years after July 1, 1952) is taken in clinical pathology in institutions that are approved for the deficiency of training required.

Minimum: 175 autopsies and 1,500 surgical specimens for three residents. Additional resident for each 50 autopsies or 500 surgical specimens.

Category F. In pathological anatomy only, for two years. Candidates taking training in these institutions will not be eligible for certification in clinical pathology unless they take one additional year full time in clinical pathology (two years after July 1, 1952) in institutions that are approved for the deficiency of training required, and will be eligible in pathological anatomy only if another year is taken in another institution that is approved for one or more years in pathological anatomy.

Minimum: 125 autopsies and 1,250 surgical specimens for two residents. Additional resident for each 50 autopsies or 500 surgical specimens.

Category G. In pathological anatomy only, for one year. Candidates training in these institutions will not be eligible in both pathological anatomy and clinical pathology unless they take an additional year in pathological anatomy and an additional year (two years after July 1, 1952) in institutions that are approved for these periods of training. Candidates seeking certification in pathological anatomy only must study an additional two years in institutions that are approved for that period of training.

Minimum: 75 autopsies and 1,000 surgical specimens for one resident. Additional resident for each 50 autopsies or 500 surgical specimens.

Category H. For postmortem part of pathological anatomy for two years. Credit is never allowed for more than two years. Candidates taking training in these institutions may pursue further training as follows: 1. For pathological anatomy only. An additional year in an institution in Category A, B, C, E, F, or G with assignment to surgical pathology principally. 2. For pathological anatomy and clinical pathology. An additional year (two years after July 1, 1952 in an institution in Category A, B, C, L, M, or N with assignment to clinical pathology and one-half year assigned to surgical pathology principally, in an institution in Category A, B, C, or J.

Minimum: 125 autopsies for two residents. An additional resident for each 60 autopsies.

Category I. For postmortem part of pathological anatomy for one year. Candidates taking training in these institutions may pursue further training as follows: 1. For pathological anatomy only. An additional two years in an institution in Category A, B, C, E, F, or G with general assignments. 2. For pathological anatomy and clinical pathology. An additional year (two years after July 1, 1952) in an institution in Category A, B, C, L, M, or N with assignment to clinical pathology and one year to an institution in Category A, B, C, E, F, or G.

Minimum: 75 autopsies for one resident.

Category J. Surgical pathology part of pathological anatomy for one year. Credit is never allowed for more than one year and the director of the laboratory must hold the certificate of the American Board of Pathology in pathological anatomy or be eligible for certification. Candidates training in these institutions may pursue further training as follows: (1) For Pathological Anatomy only. An additional two years in an institution in Category H or in an institution in Category A, B, or C with assignment to postmortem pathology only. (2) For Pathological Anatomy and Clinical Pathology an additional year (two years after July 1, 1952) in an institution in Category A, B, C, L, M, or N with assignment to clinical pathology full time, and an additional year to an institution in Category A, B, D, E, F, G, or H with assignment to postmortem pathology full time.

Minimum: 2,000 surgical specimens for one resident. An additional resident for each 1,000 surgical specimens.

Category K. Special pathology as part of pathological anatomy. Credit for not to exceed one-fourth the time credit (one year if seeking certification in pathological anatomy only, six months if seeking both pathological anatomy and clinical pathology) of candidates applying in pathological anatomy may be taken in special laboratories with limited activities such as neuropathology, orthopedic pathology, ophthalmic pathology, etc. The candidate who receives credit in this category may, on request, have the field of special pathology designated on the certificate of the board.

Category L. Clinical pathology for three or more years. Candidates taking three years of training in these institutions will not be eligible for pathological anatomy unless they take an additional two years in institutions approved for pathological anatomy.

Minimum: 100,000 tests in clinical pathology for three residents. Additional resident for each 50,000 tests.

Category M. Clinical pathology for two years. Candidates taking two years' training in these institutions must take the same additional training as in Category L to be eligible for pathological anatomy also. To be eligible for clinical pathology only, an additional year of clinical pathology must be taken in an approved institution.

Minimum: 75,000 tests in clinical pathology for two residents. An additional resident for each 50,000 tests.

Category N. Clinical pathology for one pear. Candidates taking training in those institutions must take an additional two years in an institution in Category A, B, C, L, or M assigned to clinical pathology for eligibility in clinical pathology only. To be eligible in pathological anatomy and clinical pathology, an additional two years in approved institutions is required.

Minimum: 50,000 tests in clinical pathology for one resident.

Category O. Special clinical pathology as part of clinical pathology. Candidates applying for clinical pathology only may receive credit for not in excess of one-quarter of the training period (one year if seeking certification in clinical pathology only, six months if seeking both pathological anatomy and clinical pathology) for work in a special field of clinical pathology, such as bacteriology, serology, etc. Under these circumstances, on request, the special field will be designated on the certificate of the board.

Category P. Research: Residence in certain institutions in which full time is devoted to research with a direct application to the practice of pathological anatomy or clinical pathology may be accepted for credit not to exceed one-third the time requirement (20 months if no clinical internship, 16 months if a clinical internship was taken). The board encourages research and believes that all candidates should carry on investigation during their training in all institutions. Therefore, this category is only for those wishing to do full time research.

AMERICAN BOARD OF PEDIATRICS

Lee F. Hill, President, Des Moines, Iowa
James Marvin Baty, Vice-President, Boston
Robert B. Lawson, Secretary-Treasurer, Miami, Fla.
John A. Bigler, Chicago
James G. Hughes, Memphis, Tenn.

J. A. Johnston, Detroit
Waldo E. Nelson, Philadelphia
Ralph V. Platou, New Orleans
A. Ashley Weech, Cincinnati
John McK. Mitchell, Executive Secretary, 6 Cushman Rd., Rosemont, Pa.

REQUIREMENTS FOR CERTIFICATION[*]

All candidates for examination for certification must meet the following requirements:

1. Graduation from an approved medical school.
2. Hold a license to practice in the United States prior to issuance of a certificate except in those situations in which a license to practice is not required.
3. One year of rotating, pediatric, or other internship in an approved hospital.
4. Two years of specialized residency-type training in an approved pediatric center.

At least one year of the two years of required residency training must be a full-time medical pediatric inpatient residency or internship in an approved institution. The second year of required residency training may be met in the ways listed below, although the board recommends that whenever possible candidates complete the two years as regular residents.

(a) Graduate School courses will be accepted only in exceptional cases by prior arrangement, up to a maximum of nine months.

(b) A maximum of three months' credit each is allowed for full-time residency type training in allied pediatric subjects such as pediatric allergy, pediatric psychiatry, pediatric pathology, pediatric radiology, newborn service, etc.

(c) A maximum of six months' credit is allowed for residency training in an approved contagious disease hospital.

5. A subsequent term of two years of specialized study or practice or a combination of the two.

Credit for one year toward this requirement is allowed for medical military service regardless of the assignment. The maximum credit that any candidate may receive toward the practice requirement for work done prior to the completion of residency training is one year.

Research residencies which involve little or no clinical training are creditable for only three months. Research residencies which include significant clinical training may be pro-rated to a total of six months for a year of service. Teaching fellowships may not be offered in lieu of residency appointments.

Both research residencies and teaching fellowships are, of course, entirely acceptable in satisfaction of the practice or further study requirement. Portions of a research residency not applicable for residency training credit may be carried over for practice credit.

Preceptorships are not accepted for credit toward the residency requirement, but are accepted toward the practice requirement.

GRADUATES OF MEDICAL SCHOOLS IN CANADA

Graduates of approved medical schools in Canada and those who have received their internship and residency training in pediatrics in hospitals approved by the Royal College of Physicians and Surgeons of Canada will be eligible for examination for certification under the same regulations as those trained in the United States.

GRADUATES OF FOREIGN MEDICAL SCHOOLS

Citizens of the United States.—Citizens of the United States of America who are graduates of medical schools other than those in the United States and Canada will be processed for eligibility for examination for certification if they can meet all the following requirements:

1. They are graduates of medical schools recommended by the Council on Medical Education and Hospitals of the American Medical Association.
2. They hold a license to practice in the United States.
3. They can meet the internship and residency training requirements of the board as detailed above with the following provisions:

(a) Internship and residency training must be served in hospitals approved by the board in the United States.

(b) A maximum of the internship and one year of residency training may be allowed for such experience obtained in a small list of foreign hospitals recognized by the board. The other year of residency training must be served in a straight inpatient medical pediatric residency appointment in an approved hospital in the United States.

Citizens of the United States of America who are graduates of medical schools other than those in the United States or Canada, and which are not recommended by the Council on Medical Education and Hospitals of the American Medical Association, may be accepted for examination for certification after they have passed successfully Part II of the examinations of the National Board of Medical Examiners, Inc., provided they meet all other requirements of the Board as provided in regulations governing such candidates. It should be noted that this regulation is permissive, not mandatory. Each application will be evaluated individually.

Citizens of Other Countries.—Properly qualified candidates who are permanent residents in and citizens of other countries and are licensed to practice there and who have fulfilled the residency training requirements listed above in the United States or Canada may apply for examination for certification by the American Board of Pediatrics.

Such foreign candidates who are returning to their own country at the end of their training period may be examined without completion of two full years in the practice of pediatrics. The residency training requirements must be completed in full in advance of admission to any part of the examinations.

A special certificate, appropriately identified to distinguish it from the regular certificate of this board, may be issued to such candidates who have passed successfully the examinations of this board after they have completed such a period of practice or further study in their own country which, when added to similar experience in the United States or Canada, make a total of two years of the practice of pediatrics.

INFORMATION CONCERNING EXAMINATIONS

The examinations for certification are given in two sections. Part I is written; Part II is an oral examination.

Part I—Written

Written examinations are objective in type and are given once each year, usually in January, simultaneously at a number of places scattered throughout the country, and at a few military stations abroad. Candidates must pass the written examination before admission to the oral examination will be authorized.

Part II—Oral

Oral examinations are held four to six times each year at centers offering suitable facilities, in locations determined by proximity to the largest number of eligible candidates. One examination session each year is scheduled at a location closer to candidates from some less populous area. As far as possible, candidates are given a choice of locations, taking into account the date application is filed, date of eligibility and proximity to the examination site.

Candidates who are admitted to the oral examination (Part II) will not be informed of their grade on the written portion. Their relative standing in Part I will, however, be utilized in final decision with regard to passing.

Candidates who fail after taking Part II will not be required to retake Part I but may be advised to do so in order that they may have an opportunity to improve a low score.

APPLICATION

Application must be made on special blanks, which will be furnished by the executive secretary after a preliminary survey of the applicant's training. Applications may be submitted one year in advance of eligibility date; they will not be accepted earlier. The number of candidates admitted to a given written mination will be determined by the number who can be mined orally during that year, plus a reasonable number alternates.

---

[*] To avoid misunderstanding, the board urges any candidate whose training is not clearly covered in these regulations to communicate with the office of the executive secretary. Whenever possible, this should be done before entering upon the appointment in question.

LETTERS OF RECOMMENDATION

Letters from two competent pediatricians recommending each plicant must be sent to the executive secretary of the board. se letters should not accompany the application but should sent directly to the executive secretary.

FEES

The application fee is $75.

The full fee must be remitted with the application. Refund l be made only if the applicant is refused examination for son other than failure in the same.

No additional fee is required for second and third written minations. The fee for second and third oral examinations 50 each.

CERTIFICATION IN SUBSPECIALTY OF ALLERGY

LLIAM C. DEAMER, Chairman, San Francisco
OME GLASER, Rochester, N. Y.
ORGE B. LOGAN, Rochester, Minn.
RRY L. MUELLER, Boston
ES OVERALL, Nashville, Tenn.
T RATNER, New York

he American Board of Pediatrics has established certifica- in allergy as a subspecialty of pediatrics.

ll candidates must pass the written and oral examinations in iatrics before submitting an application for examination in rgy.

ach allergy application is individually considered and must accepted by the subspecialty board.

INFORMATION CONCERNING EXAMINATIONS

llergy examinations consist of written and oral portions. The tten examination will be given once a year under a local nitor and must be passed before admission to the oral ex- ination will be authorized. Oral examinations will be held times and places designated by the chairman of the sub- cialty board. Ample notice will be sent to candidates by the cutive secretary.

FEES

he application fee for certification in allergy is $100.

The full fee must be remitted with the application.

No additional fee is required for second and third written ex- inations. The fee for second and third oral examinations is each.

pplication forms will be forwarded on request to the office the Executive Secretary of the American Board of Pediatrics should be returned to that office when completed. All respondence should be addressed to him.

REQUIREMENTS

. Certification in pediatrics.
2. Two years full time of approved allergy residency or fel- ship training in an approved clinic and its hospital, or
3. One year full time of approved allergy residency or fel- ship training and two years, part-time, 200 hours a year in approved clinic and its activities, or
4. Five years, part-time, 200 hours a year in an approved rgy clinic and its activities.
5. Preceptorship alone is not acceptable, but a resident or low doing full-time work in allergy may spend part of his ne working with private patients in the hospital or in the ice of an allergist qualified to give this training.

Until clinics are officially approved, the candidate should as- e himself that the clinic is satisfactory for training by writing the executive secretary of the Board of Pediatrics. In general h clinics will be in hospitals that have been accepted by the uncil on Medical Education and Hospitals of the American edical Association and by the American Board of Pediatrics training in pediatrics, or have been approved for training allergy by the Board of Pediatric Allergy or of Internal edicine.

Under all methods of study there must be presented evidence serious work in research or clinical investigation.

The candidates must be prepared for a searching examination in the theory and practice of allergy. This will include the theory of the underlying mechanisms, animal experimentation, the clinical manifestations in the so-called allergic diseases, especially as they appear in infants and children, and also the allergic factors that may be present in other diseases. They must be prepared to discuss the important diagnostic procedures and methods of treatment and, in controversial matters, they must be familiar with the arguments on both sides of the questions.

CERTIFICATE

When accepted the diplomate will receive from the American Board of Pediatrics a certificate in allergy and will be listed as a specialist in allergy.

Prospective applicants for certification in the subspecialty of allergy may apply to the executive secretary of the American Board of Pediatrics.

AMERICAN BOARD OF PHYSICAL MEDICINE AND REHABILITATION

ROBERT L. BENNETT, Chairman, Warm Springs, Ga.
WILLIAM H. SCHMIDT, Vice-Chairman, Philadelphia
ARTHUR S. ABRAMSON, New York
DONALD A. COVALT, New York
O. LEONARD HUDDLESTON, Santa Monica, Calif.
H. WORLEY KENDELL, Peoria, Ill.
A. B. C. KNUDSON, Washington, D. C.
FREDERIC J. KOTTKE, Minneapolis
DONALD L. ROSE, Kansas City, Kan.
ARTHUR L. WATKINS, Boston
EARL C. ELKINS, Secreary-Treasurer, 200 First St. S.W.,
Rochester, Minn.

QUALIFICATIONS

A. Satisfactory moral and ethical standing in the profession.

B. A legal license to practice medicine in one or more of the states of the United States, its territories, the District of Columbia, or one or more of the provinces of Canada.

C. Graduation from a medical school approved by the Council on Medical Education and Hospitals or graduation from a foreign medical school which, in the opinion of the board, offers medical education equivalent to such an approved school; completion of an internship in a hospital approved by said Council.

D. A period of study after the internship of not less than thre years in a residency approved by the above mentioned Council. This period of study shall include graduate training in basic sciences as related to physical medicine and rehabilitation and not less than two years of clinical training and experience in physical disabilities related to the fields of rheumatology, neurology, neurosurgery, orthopedics, and medicine.

E. An additional period of not less than two years in full time practice of physical medicine and rehabilitation.

Training in approved residency programs in closely allied medical-surgical fields may be acceptable in part (for "D" above), but such credit is limited and based on individual interpretation by the board.

In selected cases, a candidate may be deemed eligible for examination on the basis of eight years of full time practice in physical medicine and rehabilitation (as a substitute for "D" and "E" above).

EXAMINATION

The examination for certification is given in two parts. Part I is written, part II, oral. Examinations are given once a year and cover certain aspects of the basic sciences and the clinical aspects of physical medicine and rehabilitation (including the role of associated personnel such as the physical therapist, occupational therapist, clinical psychologist, social service worker, and vocational guidance counselor).

APPLICATION

The application form shall contain a record of the candidate's premedical and medical education, internship, graduate study, and verification of full time practice in the specialty. The application shall be accompanied by a fee of $100, which will cover the evaluation and both the written and oral examination. (In case of rejection of application, $85 will be refunded. The remaining $15 constitutes the evaluation fee.)

CERTIFICATION

Certificates of the board shall be issued to the effect that the applicant has been found qualified as a specialist in physical medicine and rehabilitation.

AMERICAN BOARD OF PLASTIC SURGERY

Frederick A. Figi, Chairman, Rochester, Minn.
S. Milton Dupertuis, Vice-Chairman, Pittsburgh
Truman G. Blocker Jr., Galveston, Texas
Albert D. Davis, San Francisco
William H. Frackelton, Milwaukee
Paul W. Greeley, Chicago
James B. Johnson, Beverly Hills, Calif.
Edward A. Kitlowski, Baltimore
Jacob J. Longacre, Cincinnati
Robert E. Moran, Washington, D. C.
Gerald B. O'Connor, San Francisco
Kenneth L. Pickrell, Durham, N. C.
Lyndon A. Peer, Newark, N. J.
Clarence R. Straatsma, New York
Frank McDowell, Secretary-Treasurer, St. Louis
Mrs. Estelle E. Hillerich, Corresponding Secretary,
4647 Pershing Ave., St. Louis 8, Mo.

GENERAL REQUIREMENTS

1. Moral and ethical standing in the profession satisfactory to the board.

The board, believing that the practice of "fee splitting" is pernicious, leading as it does to traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

2. Those whose activities are limited to the practice of plastic surgery.

3. This board will accept as applicants for examination only those who are full citizens of the United States or Canada. Notarized statements, not original citizenship papers, attesting to the fact of full citizenship in the United States or Canada must be furnished by foreign-born applicants when the application is filed. Such candidates must have at least two years of practice in plastic surgery in North America after completing the training required by the board.

PROFESSIONAL REQUIREMENTS

The board considers the requirements outlined below to be minimal in attaining its purposes and encourages candidates to take advantage of broadening experience in other fields. Candidates must fulfill the requirements that are in force at the time of their examination and/or certification.

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school considered acceptable by the board.

2. Completion of an internship of not less than one year in a hospital approved by the same Council.

3. Two years of postgraduate work in general surgery, beyond the intern year, as a resident or an assistant resident in a hospital approved by the same Council.

4. Training in general plastic surgery, including maxillofacial surgery, for an additional period of not less than two years in a residency approved by the same Council, or in a preceptorship approved by the Board. In fulfilling this requirement, there is a limit of one year's credit given for all work done in all governmental plastic surgery residencies (Army, Navy, Veterans Administration hospital, etc.) regardless of the time put in by trainees in such residencies. It is required that all such trainees take one additional year of approved training in plastic surgery in a civilian residency or preceptorship.

5. During these years of training following the internship year, a candidate must hold positions of increasing responsibility for the care and management of patients with surgical conditions. When a candidate receives his training in more than one institution, it is equally imperative that he hold positions of increasing responsibility. He must have sufficient operative experience to acquire surgical skill and judgment through the performance of surgical operations with a high degree of responsibility, but under circumstances providing adequate opportunity for consultation and advice.

6. An additional period of not less than two years of practice in plastic surgery. If a candidate elects to spend one or two additional years in approved training in plastic surgery, one year of such training will be credited toward the required two years of private practice if it can be demonstrated that the candidate held a position of increasing responsibility. It is imperative that one year be in actual private practice in such instances.

The Board gives credit *only* for training in plastic surg received in the United States or Canada, but may, at its cretion, give credit towards the required private practice p for training in plastic surgery received in countries other t the United States and Canada, each case being determi individually.

The above training in plastic surgery may be taken resident in an approved hospital or under an approved ceptorship offering equivalent training (a list of currentl proved preceptorships is available from the board office) the latter statement it is meant that one may secure the n sary and specified training as an assistant to an accre plastic surgeon provided suitable facilities for the educati the candidate are offered.

The period of special training should emphasize the re of the basic sciences—anatomy, pathology, physiology, bio istry, bacteriology—to the application of surgical pri which are fundamental in all branches of surgery, and esp to plastic surgery. In addition, the candidate must und and be trained in the following subjects: the care of em cies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, etc.

The board reserves the privilege of requesting lists of operations done solely by the candidate for one or more years, or of requesting special and extra examinations, written or oral and practical, and of requesting any specific data concerning the candidate that may be deemed advisable before making final decision for certification.

Eligibility rulings or an evaluation of a candidate's qualifications or training cannot be made by the secretary or by any one member of the board. Official evaluations of qualifications are made only by the committee on credentials and requirements, or by the entire board where necessary, after a review of the candidate's formal application for such rulings. The applicant must allow at least two months for such requests make the rounds of the committee.

TRAINING FACILITIES

Residencies.—The American Board of Plastic Surgery, in operation with the Council on Medical Education and Hospit of the American Medical Association and the American Coll of Surgeons, evaluates training facilities in institutions provid acceptable residencies in plastic surgery. The board does assume the responsibility for independent inspection and proval of residencies. It will inspect and make recommendati for or against approval of a residency in plastic surgery after the director of the residency has applied to the Reside Review Committee in Plastic Surgery of the Council on M ical Education and Hospitals of the American Medical Ass tion for approval of the residency, and after the Council notified the board to that effect. Therefore, any diplomat the board wishing approval of a residency under his supervi should apply to the Council for such approval.

The board will make its own inspection, preferably at same time as the American Medical Association Counci spection, and will report its findings to the Council. Upon pletion of consideration by the Council and the board hospital will be notified by the Council of the joint action has been taken, and the hospital and the secretary of the b will be notified simultaneously by the Council to avoid misunderstanding as to the status of the program.

Preceptorships.—In certain instances the board will accept, in lieu of the required two years' training in an approved residency, training in an approved preceptorship under a fully qualified plastic surgeon when such preceptorship is properly organized and supervised to give the trainee adequate experience and training in plastic surgery of a well-rounded nature. Trainees will be required to keep a detailed record of their experience, presenting this report to the board annually on a report form supplied by the board on request. In preceptorship programs of training it would be well for the preceptor to report annually to the board the name and qualifications of any preceptee under his supervision and the work done by the preceptee. Neither the board nor its individual members can be responsible for the placing of applicants for training. The board considers those residencies approved by the Council on Medical Education and Hospitals of the American Medical Association as acceptable facilities for training in plastic surgery.

It should be kept in mind by all that the primary interest of the board is to encourage well-rounded training in plastic surgery with the aim of producing plastic surgeons capable of doing good work in the wide variety of cases which may come under their care. The standards set up by the board, both for preliminary general surgery and for specialized plastic surgery training, are established in an effort to further this aim. The quality of the training received should be reflected in the candidate's ability to achieve good results in his practice, and the examinations of the board are an attempt to judge the ability of the candidate in the specialty of plastic surgery.

Before training in plastic surgery is begun, the plastic surgeon in charge of the residency or preceptorship should ascertain that the trainee's preliminary training in general surgery meets the requirements of the board, that is, two years of residency training in general surgery after the internship year.

The training in plastic and maxillofacial surgery (at least two years) whether in a residency or a preceptorship, should cover a wide field of plastic surgery, both as to type and anatomic distribution. It should include experience in the treatment of congenital and acquired defects and deformities of the face, neck, body, and extremities, for both functional and esthetic reasons. There should be available sufficient material of a diversified nature so that the trainee will be able to pass the examinations of the board after the period of training and the two additional years of private practice. If the available material on one service is inadequate, the deficiency should be made up by affiliation with another plastic surgeon on another service so that a broad experience will be obtained in plastic surgery. The trainee should be provided an opportunity to operate under the direct supervision of the plastic surgeon in charge, and with increasing ability, should be given an opportunity to operate independently on suitable cases under more remote supervision.

MILITARY CREDIT

Credit for military service is given on an individual basis, each case being considered on its own merits and the amount of credit allowed is determined by the board when the information is submitted with the application.

The Medical Officer's Professional Training Record (DD Form 408) is a record maintained by individual Medical Corps officers for presentation to the various authorized accrediting boards toward certification. This record is presented by the officer to the boards for evaluation of the military experience acquired by Medical Corps officers while serving in the Army Medical Service. This form has been prepared by the Surgeons General of the armed services with the assistance of the Council on Medical Education and Hospitals of the American Medical Association and is distributed by the offices of the Surgeons General to their personnel. It is highly important that prospective applicants obtain a copy of this form and that it be submitted with their credentials for evaluation by the board.

CASE REPORTS

Upon approval by the board of a candidate's application for certification, each candidate is required to submit to the board 35 or more case reports illustrative of his independent work in the field of general plastic surgery.

Candidates are admitted to examination only after submitting case reports that meet the required standards of the board and that have been approved by the committee on credentials and requirements.

Case reports must be submitted within one year from the time of such request; otherwise a new application must be filed. The case reports shall conform to conditions which the board may from time to time specify.

Case reports must be received in the office of the board by January 1 for those who desire to be considered for the spring (May-June) examinations of the board and by July 1 for the fall (October-November) examinations. There will be no exceptions to these two deadlines.

The 35 case reports must be of a diversified nature and must be submitted to the office of the board together with before and after photographs. They should be of the following distribution:

1. Cleft lip: 1 to 3 cases
2. Cleft palate: 1 to 3 cases
3. Traumatic defects requiring reconstructive surgery:
   (a) Face and neck: 2 to 4 cases
   (b) Body: 1 to 4 cases
   (c) Extremities: 1 to 6 cases
4. Acute burns: 2 to 4 cases
5. Fracture of facial bones, excepting nasal fractures: 1 to 3 cases
6. Esthetic operations of sufficient variety: 6 to 12 cases
7. Plastic surgery of the hand: 2 to 4 cases
8. Malignancies, or conditions prone to malignancies (eradication and repair):
   (a) Face: 2 to 4 cases
   (b) Body: 1 to 3 cases
   (c) Extremities: 2 to 4 cases
9. Congenital anomalies: 1 to 6 cases
   (a) Examples:
      (1) Syndactylism
      (2) Congenital absence (partial or total) of external ear
      (3) Hypospadias
      (4) Bands (constricting)
      (5) Thyroglossal duct cyst
      (6) Extensive nevi, etc.

If the case reports and lists of operations are approved, the candidate will receive subsequent information regarding taking the examinations. The board at its discretion may request certification of case reports by the hospital where the operations were performed. The following form should accompany the case reports: "I hereby certify that the planning and essential surgical procedures described herein were carried out by me as an independent operator."

Every candidate's final acceptability for examination is based not only on the evaluation of his training qualifications, but on his professional ability as a plastic surgeon, his ethical standing in the community, and the strict limitation of his work to plastic surgery.

A candidate should remember that these case reports are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his ability.

EXAMINATIONS

In instances where a candidate submits case reports that do not meet the standards of the board, he will be required to submit additional case reports or an entirely new set of 35 within a period of one year. If this second series of case reports again do not meet the standards of the board, the candidate may be required to take additional training (of length and type specified by the board) before he will be allowed to submit any further case reports.

After a candidate has been notified that he has fulfilled the preliminary requirements and that his case reports have been approved, he will be required to take the qualifying examination within a period of three years.

After approval of the case reports, and prior to the examination, the candidate will be visited at his place of practice by a member or members of the board to observe him operate and to examine a number of his pre-operative and post-operative cases.

The qualifying examinations are given twice yearly, in the spring and fall. The spring examination is given immediately preceding, during, or following the annual meeting of the American Association of Plastic Surgeons (usually in May), and the fall examination is given immediately preceding, during, or following the annual meeting of the American Society of Plastic and Reconstructive Surgery (usually in October). Candidates are required to go to the designated center for the qualifying examination, which will last three days. These centers will be the city in which the meetings of these two organizations are held if the proper clinic and hospital facilities are available, otherwise in some nearby city where such material is available. Arrangements for all examinations are made by the examination committee.

A written examination will consume all of the first day and half of the second day. An oral and practical examination will consume the afternoon of the second day and all of the third day. The subjects of the written examination are (1) theory and practice of plastic surgery, (2) applied anatomy, applied physiology, (3) pathology, bacteriology, clinical laboratory methods (pharmacology), (4) reaction of tissue to injury, surgical accidents, anesthesia. A general oral examination pertaining to plastic surgery will be given. In the practical part of the examination, the examiners will present a group of patients for examination by the candidates, and the candidates will be quizzed on methods of procedure—diagnosis, treatment, technique, and so on. Slides of preoperative conditions will be shown on a screen and the candidate asked to make a quick diagnosis of the items and to tabulate in the order of their importance the methods of treatment. Microscopic slides of the average pathological tissue falling within the province of the plastic surgeon will be given the candidates, and they will be asked to write a description and diagnosis.

GRADES

To be considered as passing, the candidate will be required to receive a grade of at least 65% in each portion of the written examination and an average grade of 75% on the entire written and oral examination.

CERTIFICATION

After a candidate has met the requirements for eligibility and passed the examinations of the board, a certificate attesting his qualifications in plastic surgery will be issued to him by the board, signed by its officers and having the seal of the board affixed thereto. It shall be the prerogative of the board to determine the fitness professionally and ethically of any candidate for its certificate, and the action or decision of the board regarding the certification of any candidate shall be final.

FEES

The fee for application and examination is $150. Of this sum, $25 must accompany the application and the remaining $125 must be paid when the candidate is notified of acceptance for examination. There will be no refunds. This fee may be increased at the discretion of the board. The board is a nonprofit organization, and the fees of candidates are used solely for defraying the actual expenses of the board. The members of the board serve without remuneration. Because of the limited number of surgeons certified by this board it is necessary for a limited time to request a voluntary annual contribution of $10 from diplomates after the first year's certification to help defray expenses.

AMERICAN BOARD OF PREVENTIVE MEDICINE

Ernest L. Stebbins, Chairman, Baltimore
V. A. Van Volkenburg, Vice-Chairman for Public Health,
  Albany, N. Y.
Robert A. Kehoe, Vice-Chairman for Occupational Medicine,
  Cincinnati
Otis O. Benson, Vice-Chairman for Aviation Medicine,
  Washington, D. C.
Gaylord W. Anderson, Minneapolis
J. H. Baillie, Toronto, Canada
Richard F. Boyd, San Francisco
LeRoy E. Burney, Washington, D. C.
A. G. Kammer, Pittsburgh
Matthew R. Kinde, Battle Creek, Mich.
Langdon C. Newman, Washington, D. C.
James H. Sterner, Rochester, N. Y.
Jan H. Tillisch, Rochester, Minn.
Felix J. Underwood, Jackson, Miss.
Tom F. Whayne, Secretary-Treasurer, University of Penn
  vania, Philadelphia 4, Pa.

ELGIBILITY REQUIREMENTS

Except as mentioned later, each applicant for a Certificate Public Health, Aviation Medicine or Occupational Medicine required to meet certain eligibility requirements and to pas examination. Such eligibility requirements are set forth in by-laws of the Board. For the information of applicants su requirements are briefly outlined below; but for a full statem thereof reference must be made to the by-laws, as from tim time in force, by which alone such requirements are govern

GENERAL REQUIREMENTS

1. Good moral character and high ethical and professio standing;
2. Graduation from a medical school in the United States Canada approved by the Council on Medical Education a Hospitals of the American Medical Association, or from a eign school satisfactory to the Board;
3. An internship of at least one year in a hospital appro by the Council on Medical Education and Hospitals of American Medical Association or in a foreign hospital sa factory to the Board; and
4. Licensure to practice medicine in the United States or the Dominion of Canada.

SPECIAL REQUIREMENTS IN PUBLIC HEALTH

1. Successful completion (after internship) of at least academic year of graduate study leading to the degree of Mas of Public Health or an equivalent degree or diploma; or tra ing or study deemed by the Board to be substantially equival to such graduate study;
2. *Residency (after internship) of at least two years of f experience in general public health practice, which inclu planned instruction, observation, and active participation in comprehensive, organized, public health program, one year which may be an approved clinical residency in a field dire related to public health;
3. A period (after internship) of not less than three years, addition to 1 and 2 above, of special training in or teaching practice of public health; and
4. Limitation of practice to full-time teaching or practice public health as a specialty.

SPECIAL REQUIREMENTS IN AVIATION MEDICINE

1. Successful completion (after internship) of at least academic years of graduate study in preventive medicine a aviation medicine, one year of which graduate study shall be a school of public health accredited for the purpose of su graduate study by the American Public Health Association a one year of which shall be in a school of aviation medicine credited for the purpose of such graduate study by the Coun on Medical Education and Hospitals of the American Medi Association; or training and study deemed by the Board to b substantially equivalent to such graduate study.
2. *Residency (after internship) of at least one year o supervised experience in aviation medical practice, which in cludes planned instruction, observation, and active participati in a comprehensive, organized program of aviation medicine,
3. Supervised practice of aviation medicine (after internship of not less than one year, in addition to 1 and 2 above, of speci training in or teaching or practice of aviation medicine;

---

*Approval of Residency training is in the process of develo ment. Until such time as an adequate program of Residency i developed, field training will be evaluated by the Board on a individual basis. Information as to approved residencies may b obtained from the Council on Medical Education and Hospit or from the Secretary of the Board.

4. A period (after internship) of not less than two years, in dition to 1, 2 and 3 above, of special training, teaching, re-rch or practice of aviation medicine;

5. Limitation of practice to full time teaching, research or actice of aviation medicine;

6. Regular and frequent participation in aerial flight.

Credit for training and experience in public health or aviation dicine while in military service will be considered on an indi-dual basis depending on the type of service.

SPECIAL REQUIREMENTS IN OCCUPATIONAL MEDICINE

1. Successful completion (after internship) of at least two ademic years of graduate study in preventive and occupa-nal medicine in a school of medicine, or a school of public alth. The schools in which such instruction is provided shall accredited for graduate study by the Council on Medical ducation and Hospitals of the American Medical Association the American Public Health Association, in accordance with e jurisdictions of these accrediting agencies; or training and udy deemed by the Board to be substantially equivalent to ch graduate study.

2. Completion (after internship) of not less than one year, in ldition to 1 above, of supervised experience (residency) in oc-pational medical practice in an industrial or medical organiza-on. This residency shall provide planned instruction, observa-on and active participation in a comprehensive program of cupational medicine; or a comparable period of experience emed by the Board to be substantially equivalent to such year supervised experience.

3. A period (after internship) of not less than three years, addition to 1 and 2 above, of special training in or teaching practice of occupational medicine.

4. Limitation of practice to full time teaching, research, or actice of occupational medicine.

APPLICATIONS

Each application for examination must be made on the pre-ribed form (which may be obtained from the Secretary), and accompanied by the required documentation and must be ed with the Secretary, ordinarily not less than 90 days prior to e date of examination. The application must also be ac-mpanied by the application fee and two recent, clear, un-ounted, autographed photographs of the applicant one of hich should be attached to the application and the other un-tached.

FEES

The fee for application and examination is $90, payable as dicated below; additional fees are payable for re-examination, it no additional fee is payable for issuance of a Certificate.

Application fee................$15.00. No application will be con-dered unless accompanied by the application fee. The applica-on fee is not refundable.

Examination fee............$75.00. This fee is payable when the plicant is notified of acceptance for examination, and, if paid ior thereto, is not refundable after such notification has been ven.

No member of the Board is authorized to give informal opin-ns as to the eligibility of candidates. The determination of gibility will be made only by the Board after receiving full plication information. Each candidate must comply with oard regulations in effect at the time the examination is taken nd also those in effect at the time the Certificate (if any) is sued, regardless of when his original application was filed. An plicant declared ineligible for admission to examination may file or reopen his application on the basis of new or additional formation within two years of the filing date of his original pplication without payment of an additional application fee.

Applicants who are declared eligible for examination but who il to submit to examination within three years of the date of e filing of the application are required to file a new application nd pay a new application fee.

EXAMINATIONS

Examinations will be held from time to time and in various laces depending upon need as indicated by applications re-eived. Examinations will ordinarily be held in connection with the annual meetings of one or more of the sponsoring societies and may also be held at other times and other places so located geographically as to minimize travel for the applicants.

The examination consists of three parts:

Part 1 consists of a comprehensive written examination designed to test the knowledge of the applicant in the general field of preventive medicine. Part 2 is a comprehensive written examination designed to test the knowledge of the applicant in the special field in which he requests certification. Part 3 is an oral or practical examination which will usually be held at the completion of the written examinations. An endeavor will be made to adapt the details of the oral or practical examination to each candidate's experience and practice. The examiners will report upon each candidate to the assembled Board, by which the results of the examination will be considered.

CERTIFICATION

Upon satisfactory completion of the examination and proof to the satisfaction of the Board that the applicant is eligible for certification, a Certificate will be issued to the effect that the applicant has been found to be possessed of special knowledge in the field specified in his application. The Certificate will be signed by officers of the Board and will have its seal affixed. Each Certificate remains the property of the Board, but the person to whom it is issued is entitled to its possession unless and until it is revoked. Any Certificate issued by the Board may be revoked if evidence, satisfactory to the Board, is presented that the applicant was not eligible to receive it at the time of application or issuance, or that he misstated, misrepresented or concealed any pertinent fact, or that his license to practice medicine has been suspended or revoked, or that he has ceased to be engaged in the teaching or practice of the specialty in which he has been certified. The issuance of a Certificate to any person does not constitute such person a member of the Board.

PLEDGE

Each candidate is required to sign the following pledge.

"I hereby pledge myself to the highest ethical standards in the practice of" the specialty.

The above requirements for certification are undergoing revision at the present time. Communications regarding such revisions should be addressed to the Secretary of the American Board of Preventive Medicine.

AMERICAN BOARD OF PROCTOLOGY

Harry E. Bacon, President, Philadelphia
Hyrum R. Reichman, President Elect, Salt Lake City
A. W. Martin Marino, Vice President, Brooklyn, N. Y.
Garnet W. Ault, Washington, D. C.
Frederick B. Campbell, Kansas City, Mo.
Walter A. Fansler, Minneapolis
Louis E. Moon, Omaha
Robert J. Rowe, Dallas, Texas
R. A. Scarborough, San Francisco
Stuart T. Ross, Secretary, 520 Franklin Ave.,
Garden City, N. Y.

QUALIFICATIONS AND REQUIREMENTS

General

All candidates shall comply with the following regulations:

1. A candidate shall possess moral, ethical and professional qualifications acceptable to the Board.

2. He shall possess full citizenship in the country where he practices.

3. He shall limit his practice to proctology, shall appear personally before the Board and shall submit to the required examinations.

4. He shall deliver to the Board upon request an official record of patients hospitalized by him during the year prior to the date of submission of the application.

5. He shall submit a bibliography of papers and books published by him.

Professional Qualifications

1. He shall be a graduate of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.
2. He shall possess a license to practice medicine in the country of his residence.
3. He shall have completed an internship, preferably of the general rotating type, of not less than 12 months in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

Special Professional Qualifications

He shall have completed:

1. Two years of approved general surgical residency and two years of approved proctologic residency; or
2. Three years of approved general surgical residency and one year of approved proctologic residency by special arrangement with the Board; or
3. Three years of approved general surgical residency and two years of approved proctologic preceptееship by special arrangement with the Board; or
4. Two years of approved general surgical residency and three years of approved proctologic preceptеeship.

APPLICATIONS

Each candidate for examination shall submit an application prepared upon the prescribed form which may be obtained from the Secretary of the Board. It shall contain a record of the candidate's premedical and medical training, internships, residencies, preceptееships, other post-graduate study, hospital and dispensary appointments, teaching positions, service in the Armed Forces, service in federal, state or local government, membership in medical societies and any additional information considered valuable by the Board.

The application shall be signed by two proctologists. It shall be accompanied by two unmounted autographed recent photographs of the candidate, letters of endorsement from appropriate sources and the application fee. It shall be filed with the Secretary not less than 90 days prior to the date of examination.

EXAMINATIONS

Examinations are conducted at times and places determined by the Board and are announced in The Journal of the American Medical Association.

Seventy-five per cent is the passing grade on all examinations.

Examination papers are identified only by numbers and the examiners do not know the identity of the examinees.

Part I: This consists of a comprehensive written examination in the basic sciences, including anatomy, physiology, pathology, bacteriology and biochemistry. The examination is held in the fall of the year simultaneously in several cities of the United States.

Upon approval of the American Board of Proctology, candidates who have passed Part I examinations of the American Board of Surgery and who have completed required training in proctology may not be required to take Part I of the examinations of the American Board of Proctology.

Part II: This is a practical examination which is held in the community in which the candidate conducts his professional activities. (It may be omitted at the discretion of the Board, in which case the candidate will be notified by the Secretary.) It is endeavored to arrange the examination at a time suitable to both the candidate and the examiner. The examination includes inspection of:

1. Surgical operations.
2. Hospital rounds.
3. Hospital and office records.
4. Office practice.

Part III: This consists of comprehensive written and oral examinations on the theory and practice of proctology, and includes roentgenologic interpretation. The examination is usually held in the fall of the year in one designated city of the United States. The candidate is not admitted to Part III examinations until he has completed the requirements of Part II.

The oral portion of the examination is conducted by mem of the Board or its designated examiners. An attempt is made t ascertain the *candidate's* knowledge of current procto literature, his knowledge of the basic sciences, and the ext of his clinical experience and other qualifications.

FEES

Application fee: A fee of $25.00 shall accompany the appl cation.

Examination fee: A fee of $150.00 is due and payable wh the candidate is notified that he has been approved for examination.

No fee shall be returned to the candidate without Board approval.

All fees shall be made payable to The American Board o Proctology and shall be sent to the Secretary.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOG

George N. Raines, President, Washington, D. C.
Paul I. Yakovlev, Vice-President, Boston
Harvey Bartle Jr., Philadelphia
C. H. Hardin Branch, Salt Lake City
Henry W. Brosin, Pittsburgh
Russell N. DeJong, Ann Arbor, Mich.
L. M. Eaton, Rochester, Minn.
Knox H. Finley, San Francisco
Francis M. Forster, Washington, D. C.
Francis J. Gerty, Chicago
William Malamud, Boston
David A. Boyd Jr., Secretary-Treasurer
102-110 Second Ave. S. W., Rochester, Minn.

APPLICATION

An application, in order to be considered at any meeting of *the Board*, must be in the hands of the *Secretary* of the Board not less than 90 days before the date of such meeting. A proper application *form may* be obtained from the Secretary. Application may be made for certification in psychiatry or in neurology or in both *fields*. Applications will be formally considered only when made *on the* official application blank in such form as may be adopted from time to time by the Board and which accompanied by an application fee in such amount as may b fixed by the Board.

The Secretary of the Board, upon receipt of an application, shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the Secretary may deem desirable and shall verify the candidate's record from the biographical records of the American Medical Association after which he shall forward the application to the Committee on Credentials. This Committee shall consider the applicatio and other information available and *notify* the Secretar whether the application is accepted. The certification of a candidate in either psychiatry or neurology, or both, shall be approved by a majority of the members *of* the entire Board a any meeting held for such certification.

FORM OF CERTIFICATION

There shall be separate certification in psychiatry and neurology and two certifications or a *combined* certification f those qualified in both fields. The certifications shall be in su form as is approved by the Board of Directors.

GENERAL REQUIREMENTS

Each application for a certificate must establish that:

(a) He is a physician duly licensed by law to pract medicine.

(b) He is of acceptable ethical and professional stand

(c) He is now a member of the American Medical As ciation. Exceptions to the foregoing may be made at *the* cretion of the Board for good and sufficient reasons.

(d) He has satisfactorily completed adequate training psychiatry or neurology, or both, as a *specialty*.

CLASSES OF APPLICANTS

Class A

Applicants who graduated from an approved medical school before the foundation of the Board (1934) will not be held to the strict interpretation of the published requirements in formal graduate training. Under such circumstances the Board will consider the training and experience of the applicant and decide whether or not he will be admitted to the examinations. After January 1, 1954, for such graduates the Board will consider ten years of full-time acceptable experience in psychiatry or neurology in lieu of the formal training requirements. Should the candidate then apply for supplementary certification, the Credentials Committee will require five years of additional acceptable experience in the supplementary field.

Class B

Applicants who graduated from an approved medical school after 1934 shall fulfill the following special requirements.

PROFESSIONAL EDUCATION

1. Graduation from a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose medical training has been received outside the United States and Canada, such training must be satisfactory to the aforementioned Council.
2. Satisfactory completion of a year's internship approved by the same Council in General Medicine, General Surgery, Pediatrics or a rotating service.
3. The nine-month wartime internship will be accepted as an equivalent of one year.

SPECIALIZED TRAINING

Admission to the examination for certification in psychiatry or in neurology requires a total of five calendar years of training and experience, three years of which must be specialized training satisfactorily completed in approved training centers, plus two years of experience. Admission to the examination for certification in both psychiatry and neurology requires a total of six calendar years of training and experience, five years of which must be specialized training satisfactorily completed in approved training centers, plus one year of experience. The specialized training may be subdivided into two and one-half years each in psychiatry and neurology or three years in one subject and two years in the other. The required years of experience should be spent in clinical practice with major responsibility for the care of patients.

All applicants who wish to qualify for examination for certification in psychiatry or neurology under the regulations relating to training credit and who began training on or after July 1, 1956, must show that at least 24 months of their residency training have been secured in residency training programs approved for at least two years of residency training in the specialty in which they seek certification.

The training for psychiatrists should include clinical work with psychoneurotic and psychotic patients, combined with the study of basic psychiatric sciences, medical and social psychology, psychopathology, psychotherapy, and the physiological therapies, including a basic knowledge of the form, function and pertinent pathology of the nervous system. The training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training period should include instruction in the psychiatric aspects of general medical and surgical conditions and the behavior disorders of children and adolescents sufficient to develop practical ability to direct the treatment of such conditions. It should also include collaborative work with social workers, clinical psychologists, courts, and other social agencies. The training program of the candidate for certification in psychiatry should include sufficient training in neurology to enable him to recognize and to evaluate the evidences of organic neurological disease.

The training for neurologists should be based on clinical work with adults and children with neurological disorders, including the neurological complications of medical and surgical conditions. This should be combined with study of the basic neurological sciences, neuroanatomy, neurophysiology, neuropathology, and neuroroentgenology. This training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training should include sufficient training in psychiatry to enable the candidate to recognize and evaluate the common psychiatric reactions.

The Board offers the foregoing two paragraphs as an outline of desirable training. If, however, the candidate has evidence of equivalent qualifications of training and experience not in the pattern here formulated, this evidence with appropriate documentary support may be included in his application for evaluation and possible approval by the Board.

Candidates seeking certification in both neurology and psychiatry, or supplementary certification in one after being certified in the other, must submit evidence satisfactory to the Board of an additional two years of full-time basic training in the supplementary specialty.

Thus, no candidate is eligible for examination by the Board until he has completed at least five years of special training and experience in neurology or in psychiatry for a single certificate, or at least six years of special training and experience in neurology and psychiatry for certification in both neurology and psychiatry.

The Board will give not more than six months of credit for not less than six months of training in an approved training center for Internal Medicine or Pediatrics in lieu of six months of experience to candidates for the certificate in psychiatry or neurology, but not to candidates for certification in both psychiatry and neurology.

The Board will give credit for one year of training in Child Psychiatry providing it is the third year of the required three years of special training required by the Board and providing it is taken in a center approved by this Board for training in Child Psychiatry. After July 1, 1956, training credit for work in the field of Child Psychiatry may be gained only by participation in a hospital residency training program that is regularly approved. After that date, all independent training approval of psychiatric clinics for children is discontinued.

TRAINING IN THE ARMED FORCES

Training and experience credit toward requirements for examination will be granted for military duty in the Korean emergency under certain conditions. This policy relates to active military medical duty since July 1, 1950. One year of training credit will be granted for one year spent in full-time psychiatric and/or neurological duties. Additional training credit will be granted for that amount of time spent in approved training programs. Experience credit will be granted for any remaining time spent in full-time psychiatric and/or neurological assignments. Double credit will not be granted for any single period of time.

For military duty after January 1, 1954, only experience credit will be granted for full-time psychiatric and/or neurologic duties. Training credit will be granted for residency assignments in regularly approved training program.

EXAMINATIONS

Dates and places of examinations shall be set by the Board at its discretion and shall be announced in THE JOURNAL of the American Medical Association, in the American Journal of Psychiatry, in *Journal of Nervous and Mental Diseases*, and in the A. M. A. *Archives of Neurology and Psychiatry.*

Though the purpose of the examination is to test the competence of the candidate in psychiatry or neurology or both, it must not be forgotten that both these medical disciplines constitute part of the broad field of general medicine. The Board requires some proficiency in neurology on the part of those it certifies in psychiatry and vice versa, but examines the candidate in accordance with the certificate he seeks. The examinations will be of such type that no adequately trained person will fail, and yet they will be sufficiently searching so that the specialist in fact may be separated from the specialist in name. The practical examination will include the examination of patients under the supervision of the examiner. The manner of examining patients, and the reasoning and deductions therefrom, will constitute an important part of the examination. Oral and practical examinations will be given in the basic sciences with special regard to their clinical implications. Written examinations may be given at the discretion of the Board. The examination for certification in psychiatry will differ from the examination for certification in neurology.

FEES

The candidate upon filing his application shall accompany it with an application fee of $50.00, which is not returnable. If a preliminary written examination has been decreed, an additional $25.00 fee will be required at the time of the applicant's acceptance. When notified by the Secretary that he is accepted for the oral and practical examination, the candidate shall send to the Secretary an examination fee of $75.00. A candidate who has been certified in either psychiatry or neurology and who has been admitted to supplementary examination for the other certificate shall pay an additional examination fee of $75.00.

Any candidate who finds himself unable to attend an examination to which he has been admitted and does not notify the Secretary at least three (3) months before the date of the examination will forfeit his examination fee. Any candidate who fails to appear for examination within a period of three (3) years following the date of notification of eligibility for examination shall be required to submit a new application and pay the attendant fee. If a candidate dies before his certificate is issued, all fees will be returned to his estate.

AMERICAN BOARD OF RADIOLOGY

Donald S. Childs, President, Syracuse, N. Y.
B. P. Widmann, Vice-President, Philadelphia
James W. J. Carpender, Treasurer, Chicago
Robert P. Barden, Philadelphia
John D. Camp, Los Angeles
E. L. Jenkinson, Chicago
Traian Leucutia, Detroit, Mich.
F. W. O'Brien, Boston
Douglas Quick, New York
Leo G. Rigler, Minneapolis
Laurence L. Robbins, Boston
Ernest H. Wood, Chapel Hill, N. C.
H. Dabney Kerr, Secretary, Kahler Hotel Building, Rochester, Minn.

CERTIFICATES

A certificate granted by this board does not of itself confer, or purport to confer, any degree, or legal qualifications, privileges, or license to practice radiology. Certificates of the board shall be issued in one of three categories:

1. *Radiology:* that branch of medicine which deals with the diagnostic and therapeutic application of radiant energy including roentgen rays, radium and radioisotopes.
2. *Diagnostic Roentgenology:* that branch of radiology which deals with the diagnostic application of roentgen rays.
3. *Therapeutic Radiology:* that branch of radiology which deals with the therapeutic application of roentgen rays, radium and radioactive isotopes.
4. *Radiological Physics:* that branch of physics which deals with the medical application of roentgen rays, gamma rays, radioisotopes, nuclear reactions, and particle accelerators.
5. *Roentgen-ray and Gamma-ray Physics:* that branch of radiological physics which deals with roentgen rays and gamma rays.
6. *Medical Nuclear Physics:* that branch of radiological physics which deals with radioisotopes, nuclear reactions and particle accelerators.

GENERAL REQUIREMENTS AND QUALIFICATIONS

Each applicant shall be required to present evidence that he has met the following standards:

1. Satisfactory moral and ethical standing in the profession.
2. A license to practice medicine in the state or county in which he resides.
3. Holds himself out to be a specialist in radiology or one of its branches as defined and devotes his time to the practice of radiology or one of its branches.
4. He is a citizen of the United States or Canada. A candidate from another country must be a permanent resident of that country and a citizen thereof.

PROFESSIONAL EDUCATION

1. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.
2. Completion of an internship of not less than one year in a hospital approved by the same Council. After completion of the internship, there shall be a period of special training (length of time as indicated below) in an approved Department of Radiology.

Radiology: Those beginning their training *before* July 1, 1956 must have three years' formal residency training in an approved Department of Radiology.

Those beginning their training on July 1, 1956, or thereafter must have three years' formal residency training in an approved Department of Radiology plus an additional year of either further training or practice. The three year training period must include the equivalent of six months (total) in Pathology and Isotopes.

Those beginning their training on July 1, 1956, or thereafter will be required to take a written examination in Physics (including Physics of Isotopes) and Pathology at the *completion* of their formal training. Acceptance for the oral examination is contingent upon passing the written examination. (The written examination in the above two mentioned phases of Radiology will abolish the oral).

Diagnostic Roentgenology: Those beginning their training *before* July 1, 1956, must have two and one-half years' formal residency training in an approved Department of Radiology. The equivalent of six months of this time must have been devoted to Pathology.

Those beginning their training on July 1, 1956, must have two and one-half years' formal residency training in an approved Department of Radiology (the equivalent of six months of which time must have been devoted to Pathology) plus an additional year of either further training or practice.

Those beginning their training on July 1, 1956, or thereafter will be required to take a written examination in physics and pathology at the *completion* of their formal training. Acceptance for the oral examination is contingent upon passing the written examination. (The written examination in the above two mentioned phases of Radiology will abolish the oral).

Those beginning their training on July 1, 1957, or thereafter will be required to take three years' formal residency training in an approved Department of Radiology—the first year of which must be spent in basic training (Pathology, Physics and Basic Radiological Techniques) followed by two years' clinical training. They will also be required to take an additional year of either further training or practice. (Written examination also required for these candidates. See above paragraph).

Therapeutic Radiology: Those beginning their training *before* July 1, 1956, must have two and one-half years' formal residency training in an approved Department of Radiology. The equivalent of six months of this time must have been devoted to Pathology.

Those beginning their training on July 1, 1956, must have two and one-half years' formal residency training in an approved Department of Radiology (the equivalent of six months of which time must have been devoted to Pathology) plus an additional year of either further training or practice.

Those beginning their training on July 1, 1956, or thereafter will be required to take a written examination in Physics (including Physics of Isotopes) and Pathology at the *completion* of their formal training. Acceptance for the oral examination is contingent upon passing the written examination. (The written examination in the above two mentioned phases of Radiology will abolish the oral). Those beginning their training on July 1, 1957 or thereafter will be required to take three years' formal residency training in an approved Department of Radiology—the first year of which must be spent in basic training (Pathology, Physics, Physics of Isotopes and Basic Radiologic Techniques) followed by two years' clinical training. They will also be required to take an additional year of either further training or practice. (Written examination also required for these candidates.)

Those applying for Therapeutic Radiology alone must show evidence of personal experience in the use of intracavitary and interstitial radium or equivalent sources, as well as proficiency in Roentgen Therapy.

Prior to July 1, 1960, those candidates desiring to be certified in either Radiology or Therapeutic Radiology, will be urged to take an examination in Nuclear Medicine.

Those candidates previously certified in Roentgenology desiring to complete their certificate in Radiology (including Nuclear Medicine) will be required to have the equivalent of six months' full-time radium and isotope training in an approved Department of Radiology.

Prior to July 1, 1960, those candidates who have been previously certified in Roentgenology and who *do not* desire to be examined in Nuclear Medicine must have the equivalent of three months' full time radium training in an approved Department of Radiology.

EXAMINATIONS

Usually two examinations are held each year. At present, examinations are practical and oral, although written examinations are to be added as noted above. The examinations are designed to test the candidate's fitness to practice radiology or one of its branches as a specialty.

The examination consists of tests in film interpretation and an oral examination in pathology, physiology, radiophysics, and radiobiology, as well as the clinical application of roentgen rays, radium, and radioactive isotopes. The applicant is also examined in "professional adaptability," in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

AMERICAN BOARD OF SURGERY

Gustaf E. Lindskog, Chairman, New Haven, Conn.
Frank Glenn, Vice-Chairman, New York
Cletus W. Schwegman, Associate Secretary, Philadelphia
John J. McKeown Jr., Assistant Secretary, Philadelphia
William A. Altemeier, Cincinnati
Joel W. Baker, Seattle
Howard H. Bradshaw, Winston-Salem, N. C.
Oliver Cope, Boston
Michael E. De Bakey, Houston, Texas
J. Englebert Dunphy, Boston
William K. Livingston, Portland, Ore.
William P. Longmire Jr., Los Angeles
Walter G. Maddock, Chicago
Carleton Mathewson Jr., San Francisco
H. William Scott Jr., Nashville, Tenn.
Harris B. Shumacher Jr., Indianapolis
William H. Snyder Jr., Los Angeles
Robert M. Zollinger, Columbus, Ohio
John B. Flick, Secretary-Treasurer, 225 S. 15th St., Philadelphia, Pa.

GENERAL QUALIFICATIONS

An ethical standing in the profession and a moral status in the community which are satisfactory to the Board.

Engagement in the practice of surgery.

PRELIMINARY TRAINING

Graduation from an approved medical school in the United States or Canada or from medical schools acceptable to the Board in other countries.

Completion of an internship (straight or rotating) of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or its equivalent in the opinion of the Board.

SPECIAL TRAINING

The American Board of Surgery is guided by the evaluation of residency training programs made by the Conference Committee on Graduate Training in Surgery and does not itself conduct such surveys.

The Board interprets the term "general surgery" in a comprehensive manner and expects candidates to have knowledge of the basic principles applied in the treatment of fractures, head injuries, or other forms of trauma, and of the more common procedures in plastic, gynecologic, orthopedic, neurologic, thoracic and urologic surgery.

BASIC SCIENCES

It is fundamental to the concept of an approved residency in general surgery that the program provide for properly organized, integrated, and progressively graded clinical training in this specialty. This presupposes a continuity of clinical experience under the supervision of the surgical staff of the hospital or hospitals in which such training is conducted. Accordingly, while recognizing the value of formal courses in the study of surgery and the basic sciences at approved graduate schools of medicine, the Board will not accept these courses as part of a three or four-year residency program in lieu of clinical experience. Furthermore, the integration of basic sciences, particularly pathology, with clinical training is considered superior to formal courses in these subjects.

SENIOR YEAR

The most important single factor in the development of a surgeon is the opportunity under guidance and supervision to grow by progressive and succeeding stages to the stature of complete responsibility for the surgical care of patients. Major operative experience and senior responsibility are essential parts of surgical education and training. For this reason the Board cannot accept for examination candidates who have not had such experience in general surgery, regardless of the number of years in training.

Since a majority of residency training programs do not provide a sufficient accretion of operative experience and personal responsibility until the completion of the senior or final year, the Board requires that the candidate have had this senior year in order to become eligible for examination. Because it is recognized that some flexibility and well-considered experimentation are essential to progress in surgical, as well as other forms of education, the Examination Committee of the Board is prepared to give individual consideration to applicants whose training in general appears adequate although it may not meet all of the following specified requirements.

Requirements for examination are subject to change and in each case are as published in the Board's most recent Booklet of Information at the time application is submitted.

TYPES OF PROGRAMS

The requirements for examination may be fulfilled by either of two programs. These are considered to be minimal in attaining the purposes of the Board and do not preclude additional desirable educational experiences which may strengthen the individual residency training program.

The Board may, at its discretion, require that a member of the Board, or other designated diplomate, observe and report upon the clinical performance of the candidate before considering his eligibility for examination or certification.

The Board reserves the right to require a candidate to submit a list of the operative procedures performed by him during his training period.

Group I Program

Completion of a graded residency in general surgery of at least four years' duration, including the senior year, in an institution or institutions acceptable to the Board and approved for four years of training by the Conference Committee on Graduate Training in Surgery is required.

An approved four-year residency may include a research project or an assignment to a basic science department such as pathology, physiology, or anatomy, provided this is an integral part of the program.

The Board accepts training of not more than one year's duration in "affiliate hospitals" as part of its basic formal educational requirements. Such "affiliate hospital" training must have been part of the graded residency program of an institution approved for four years by the Conference Committee. The senior year must have been spent in the parent institution holding the approval of the conference Committee, except in those instances where the senior year in the "affiliate hospital" is, in the opinion of the Examination Committee of the Board, equivalent in training value to the senior year in the parent institution and is under the same supervision.

The candidate who completes only four years of an approved program designed for more than four years, and [illegible] not have the senior or final year of the resi[illegible] qualifications for special consideration by the Examination Committee. The Committee can recommend acceptance of the candidate for examination in Group I or Group II, provided the evidence indicates the candidate has had adequate operative experience and clinical responsibility as certified by the Chief of Service.

Residency credit will be granted for surgical internship to a candidate who has completed a prior year of acceptable internship when the surgical internship is part of a graded program approved for four years by the Conference Committee.

Group II Program

Completion of a graded residency in general surgery of at least three years' duration, including the senior year, in an institution or institutions acceptable to the Board and approved for at least three years of training by the Conference Committee on Graduate Training in Surgery is the basic requirement.

Residency credit will not be granted for separate periods of time devoted exclusively to research or a preclinical discipline although the day to day integration of these disciplines with clinical surgery is highly desirable. The program must have included three years of clinical surgery and the final year must have been spent in the capacity of senior or chief resident in general surgery.

Two additional years of training beyond the three years of residency to complete a total of five are necessary to meet the requirements for examination. These may include:

(a) Practice of surgery under acceptable supervision (preceptorship). By "acceptable supervision" is meant an arrangement with a preceptor acceptable to the Board who should inform the Board in writing of his willingness to assume responsibility for the candidate's further training. Before the candidate's eligibility for examination can be considered, he will be required to submit to the Board a list of the operative procedures performed by him during the period of supervised practice, and the preceptor will be requested to vouch for the candidate's integrity, surgical judgment, and technical skill. The acceptance of supervised practice in fulfillment of part of the Board's requirements will be contingent upon the candidate's having had adequate clinical opportunities to fortify residency training and considerable responsibility in the care of patients, including the performance of major operative procedures under supervision.

(b) The study of surgery and the basic sciences in an approved graduate school of medicine on a full-time basis and for a consecutive period of not less than nine months, or one school year. Training credit in excess of twelve months will not be granted in this category.

If provision has been made to study a single basic science such as pathology, physiology, or anatomy, up to six months' credit may be granted for such study.

Credit may be granted for a maximum of twelve months spent in full time surgical research under a responsible investigator who is acceptable to the Board. A candidate may not claim credit for both graduate study and research years.

(c) Further acceptable surgical residency or fellowship training, either in general surgery or in a recognized surgical specialty.

Credit as outlined above under (a), (b), and (c) will be applicable only toward the two years of training which Group II candidates must complete in addition to three years of approved residency in general surgery. It will not be considered as residency credit.

MILITARY CREDIT

Credit not to exceed one year may be granted to those candidates who have served in military hospitals other than those approved for residency training, provided that the candidate has had a satisfactory surgical assignment with adequate and diversified clinical material and provided further that his work in surgery is carried out under the supervision of a surgeon acceptable to the Board. Any such credit will be considered preceptorship credit toward Group II requirements and not basic residency credit.

LICENSE TO PRACTICE

The Board requires, prior to issuance of a certificate that candidates have a valid license to practice in the nation or permanent residence except in those situations in the United States or Canada in which a license to practice is not required, such as the practice of surgery by commissioned officers in the Army, Navy or Public Health Services of these countries.

REQUIREMENTS FOR FOREIGN BORN AND FOREIGN TRAINED CANDIDATES

Such candidates must meet the same requirements as citizens of the United States or Canada. The Examination Committee may, however, in individual instances, grant credit for foreign training.

APPLICATIONS

Prospective candidates for examination by the Board should carefully read the Board's requirements. If, after becoming familiar with the requirements, a candidate needs advice about his training, or believes he has completed the requirements, he should submit a brief chronological outline of his training, including precise dates, using the Evaluation Form which will be furnished on request.

Application for Examination forms are not forwarded until candidates are within several months of completing their training and appear to have met all other requirements of the Board.

Applications should be returned to the Board's office by December 1 for candidates desiring admission to the Part I examination in March, or by July 1 for admission to the Part I examination in October.

The Board's acceptance of candidates for examination is based not only upon an evaluation of their training, but also upon information available to the Board concerning their professional ability as surgeons and their ethical standing.

Candidates are notified of their eligibility for the Part I examination as soon as their applications have been approved, and are sent a list of examination centers from which to choose. Candidates are not eligible for the Part II examination until they have made a passing grade in Part I.

EXAMINATION

The qualifying examination is divided into Part I (written) and Part II (oral). In both of these a knowledge of the practical application of the sciences fundamental to surgery is required.

Part I

The examination is given simultaneously in as many centers throughout the United States as the Board may determine suitable for the purpose and in certain military centers abroad. It will be held on the last Wednesday of October, 1957, March, 1958, and October, 1958. Thereafter the Part I examination will be held only once a year in the late Fall, at a time to be announced.

The Part I examination is of the objective, multiple-choice type, and is administered during a half-day session. This examination is designed to cover general surgical problems including the application of the basic sciences of surgery to these problems. Questions are of various types, and are based upon the analysis of case histories, cause and effect relationships, and other pertinent situations. The examinations are composed by members of the Board with the technical assistance of the Educational Testing Service.

Part II

Examinations are held in ten different centers in the United States each year from September to June inclusive. These are conducted by members of the Board and selected diplomates acting as guest examiners.

The Part II examination is oral and practical and requires the candidate's presence for one day. Candidates are examined in clinical surgery, including diagnosis, management of patients, and the application of anatomy, pathology, physiology, biochemistry, and bacteriology to surgical problems. In pathology, emphasis is placed on an understanding of disease processes and their clinical implications, as well as on the recognition of gross and microscopic lesions. The interpretation of roentgenograms also may be included.

The examination in basic sciences is integrated with clinical surgery and is not given separately.

FEES

The fee for examination is $175 payable as follows: $25 for registration, $75 for Part I and $75 for Part II.

The Board is a nonprofit organization. All fees will be used, after a reasonable amount is set aside for necessary expenses, to aid in improving existing opportunities for the training of surgeons. The members of the Board, except the Secretary-Treasurer, serve without remuneration.

CERTIFICATION IN THORACIC SURGERY

Diplomates of the American Board of Surgery wishing to become certified in thoracic surgery are advised to communicate with the Secretary of the Board of Thoracic Surgery, William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich. This Board is an affiliate of the American Board of Surgery.

BOARD OF THORACIC SURGERY

(An affiliate of the American Board of Surgery)

William E. Adams, Chairman, Chicago
John C. Jones, Vice Chairman, Los Angeles
O. Theron Clagett, Rochester, Minn.
Joseph W. Gale, Madison, Wis.
Julian Johnson, Philadelphia
Edward M. Kent, Pittsburgh
Paul C. Samson, Oakland, Calif.
Robert H. Wylie, New York
Wm. M. Tuttle, Secretary-Treasurer
1151 Taylor Ave., Detroit 2, Mich.

For current requirements for certification, communications should be addressed to the Secretary of the Board of Thoracic Surgery.

AMERICAN BOARD OF UROLOGY

Edgar Burns, President, New Orleans
Grayson Carroll, Vice-President, St. Louis
Thomas D. Moore, Memphis, Tenn.
Rubin H. Flocks, Iowa City
Donald A. Charnock, Los Angeles
William P. Herbst, Washington, D. C.
Frank C. Hamm, Brooklyn, N. Y.
Wyland F. Leadbetter, Boston
William Niles Wishard Jr., Secretary-Treasurer, Indianapolis
Mrs. Ruby L. Griggs, Executive Secretary, 30 Westwood Rd., Minneapolis 26, Minn.

REQUIREMENTS

A. Application for certification must be made on a special form. This will be provided by the secretary and must be returned to him accompanied by other required data and credentials and by $50 of the examination fee.

B. The applicant must have graduated from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association and must have completed an internship of not less than one year in a hospital approved by the same council.

Requirements of graduates of foreign medical schools shall conform to and be similar to the requirements as demanded of the applicants for the accepted medical schools in the United States and Canada. Such applications will be considered by the full board on individual merits.

C. The applicant must establish in a manner satisfactory to this Board that he is a physician duly licensed by law to practice medicine and that he is of high ethical and professional standing.

D. The applicant must establish that he has received special graduate training as follows in this order:

1. An approved internship of at least one year.
2. One year in the basic sciences or clinical studies basic to Urology; or one year residency in general surgery or internal medicine.
3. An approved graduated three-year residency in Urology, leading to competency in all its phases.

E. Applicant must have an additional period of not less than two years in the practice of Urology in the city of his office or place of practice.

F. The applicant must assure the Board that he is engaged in the full time practice of Urology.

FEE

The examination fee is $150. Fifty dollars must accompany the application. One hundred dollars must be paid when the application has been processed. Neither fee is returnable.

Applications for certification shall be examined by the credentials committee and reviewed by the board. When additional data are required to complete the application, these will be requested by the secretary.

REQUIREMENTS FOR CERTIFICATION

The requirements for certification include: evidence of hospital practice including the presentation of report of 25 representative (not necessarily consecutive) major urologic cases from practice, which must contain all items essential for diagnosis, therapy, prognosis, results of treatment, etc; a written examination; pathology and oral clinical examinations.

A. Evidences of Hospital Practice and Case Reports:

An index, in consecutive order, of all major and minor urologic surgery (including endoscopy) done during the last two years of practice must be presented. This index must be verified by the various hospital administrators.

The candidate must present 25 records of major urologic cases completed since the candidate's residency training with hospitals, names, (or initials) and record numbers in which the candidate has had complete charge, responsibility and activity in all phases of the patient's care. These reports must be typewritten on 8½ by 11 paper and in duplicate, but need not be on any special form. Please file the duplicate in your own office. This second copy will be called for when and if it is needed.

Complete index lists must accompany the reports. If they are obtained from more than one hospital a separate index list of each group should be provided. These lists must state the operator's name at the head of each page, the name (or initials) of the patient, the hospital number, and the name and date of operation. Statements from the administrators of the hospitals attesting that the candidate was the operator must be included.

The applicant must personally prepare the case reports, remembering that they are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his competence as an urologist.

The case reports must be received on or before September 1.

B. Written Examination: The written examination is designed to test the candidate's preparation in and his knowledge of the whole field of urology, including the subjects: clinical urology, pathology, anatomy, physiology, embryology, bacteriology, physiological chemistry, and endocrinology. These may be held on certain dates simultaneously in different parts of the country at places convenient for candidates.

C. Pathology: The examination in pathology will consist of the identification of gross specimens and of sections of tissue observed through the microscope. It will be held at the time of the oral examination.

D. Oral-Clinical Examination: This will consist of discussions of urologic problems. The subjects forming the basis of this examination are urography; diseases of the genital organs, including the prostate and each portion of the urinary tract and the adrenals. It will ascertain the candidate's familiarity with recent literature, the breadth of his clinical experience, and his general qualifications for practice of urology.

The professional adaptability of each candidate will be investigated in an attempt to determine his ethical conduct and his attitude toward his patients and fellow practitioners.

Even more meaningful than dollars of expenditure are the percentages of personal consumer expenditures devoted to these different items. The 1956 percentage for all medical care items was 4.5 as compared with 4.4% in 1955. The actual proportion for physicians' services alone was 1.2 in both years, whereas there was an increase from 1.2 to 1.3% for hospital services. Within the medical care field these expenditures can be better compared by treating the total expenditures for all medical care as 100 cents, the medical care dollar. The proportion of the medical care dollar being paid to physicians has declined steadily from 1929, when it was 32.7 cents, to 27.2 cents in 1955 and 27.0 cents in 1956. On the other hand, the proportion of the medical care dollar spent for hospital services has climbed rapidly from 13.7 cents in 1929 to 27.7 cents in 1955, and to 28.5 cents in 1956. Likewise, the dentists' share has steadily declined over this same interval of time.

So the general conclusion as regards the proportion of the so-called consumer budget going for medical care is that the hospitals' share has been steadily rising until it was actually the largest share in both 1955 and 1956 and the physicians' share and the dentists' share have been steadily declining. During this period of time, medical progress has occurred at an exceedingly rapid rate and the improvements in the care of patients could scarcely have been achieved without some increase in the proportion of the consumer's dollar going for hospital services.

Wage Share for Medical Care.—For employees of industrial establishments who think in terms of weekly wages this story of the relationship of inflation to medical care can be presented in still another manner, the fourth comparison. Suppose that a physician's fee for a dozen office visits or a dozen house visits would have cost an entire week's wages before World War II. The important question to the wage earner is whether the same amount of medical service would cost more than a week's wages today or less than a week's wages. For physicians' fees the answer for 1956 is 48% of a week's wages and 61% for an obstetric case. The same number of days in a hospital which would have cost a full week's wages in 1935 to 1939 would have cost 99% of a week's wages in 1956. Since such comparisons do not make allowances for the great increase in taxation, particularly in the taxes deducted from the weekly pay envelope, the standard of comparison here might be considered on a basis of the entire Consumer Price Index—say, a "market basket" containing the proper number of units of each of the items which are priced in the development of the Consumer Price Index. That standard of comparison for 1956 was 54 rather than 100%, and those items which required more than 54% of a week's wages may be considered as having been less favorable in the cost to the consumer.

Physicians' Incomes.—Turning now to the physician rather than the patient for the fifth comparison, we find that according to the U. S. Department of Commerce the average level of physicians' incomes in the United States was 122% higher in 1951 than in 1929. The average level of incomes of all gainfully employed was 125% higher. Thus during a much longer period of time the incomes of physicians and the incomes of all gainfully employed people have moved up at about the same pace. The United States Department of Commerce does not regard the studies it made of the incomes of physicians immediately before World War II as sufficiently detailed and comprehensive to provide a standard of comparison with the present levels. But that agency has made estimates for the years since 1951 and these, like the data for 1929 and 1951, show that this trend is continuing.

Other and more detailed comparisons could be made, but these five historical comparisons of the extent of inflation in the medical care sector of our national economy indicate that this sector has performed reasonably well for the consumer. Many citizens are becoming worried about the extent of inflation. As citizens, physicians should not be content to rest on their oars but should participate in discussions in their communities on ways and means to stem this dangerous inflationary tide.

Some community leaders are already suggesting buyers' strikes like those of 1919; others are urging local groups to petition the federal government to curtail spending. But if these and other attempts fail and inflation continues, it behooves the members of the medical profession to continue their efforts to moderate the ravages of inflation in the medical care sector.

DIRECTORY OF APPROVED INTERNSHIPS AND RESIDENCIES

This issue of THE JOURNAL contains the Directory of Approved Internships and Residencies together with basic information concerning the approved examining boards in medical specialties as compiled by the staff of the Council on Medical Education and Hospitals. It includes statistical data and other specific information on all hospitals recommended by the Internship Review Committee for Council approval, and those approved by the Residency Review and Conference Committees for residency and fellowship education and training. Every effort is made to present this annually revised information so that it will be current and of value to medical students, interns, residents, physicians conducting such programs, hospital administrators, specialty board personnel, and others who may utilize it for reference. The directory represents a service function of the American Medical Association specifically concerned with the increasingly important field of graduate medical education and training. The Council is deeply grateful to the hospital staff personnel and administrators, to the officers of the specialty boards, and to other organizations whose cooperation and assistance has made possible this publication.

It is of interest to note that 852 hospitals offered a total of 11,895 intern positions for the year beginning July 1, 1956. Although this represents 15 fewer hospitals than were approved in the preceding year, it represents an increase of 279 positions available. In 1956 there were 6,845 graduates from approved medical schools in the United States. However, during the same year, 9,893 (83%) of the internship positions were filled, which indicates that over 3,000 were occupied by graduates of foreign medical schools or American graduates taking more than a single year of internship. There continues to be a trend for the larger teaching hospitals to have a higher percentage of internships occupied. Hospitals in the United States territories and possessions again showed the highest percentage of filled positions (97%), and the New England area had the highest intern-occupancy rate for the continental United States (89%).

In the area of graduate medical education represented by residencies, there were 5,134 approved separate training programs offering 28,538 appointments, of which 11,950 were at first-year level. These residency training programs were offered by 1,199 hospitals in which 81% of the available positions were filled. The seven specialties of surgery, internal medicine, pathology, obstetrics-gynecology, radiology, psychiatry, and pediatrics accounted for over three-fourths of the residencies offered. The percentage of available first-year residencies filled varied from 25% in public health to 100% in aviation medicine. Fields in which less than three-fourths of the positions offered were filled include allergy, general practice, neurology, otolaryngology, pathology, physical medicine, proctology, psychiatry, public health, pulmonary disease, and radiology. With the exceptions of obstetrics-gynecology, pathology, and thoracic surgery, in which the Council on Medical Education and Hospitals approves programs in concurrence with the board concerned, all other resident training programs are approved through residency review and conference committees.

The Council presents this annual report and directory with the hope that it will be of assistance to all individuals and organizations interested in medical education at the graduate level.

BEHIND THE SCENES

There are currently 17 residency review and conference committees which function effectively as joint liaison groups of the Council on Medical Education and Hospitals with various specialty boards and, in certain instances, the American College of Physicians, the American College of Surgeons, and the American Academy of General Practice, in the evaluation and approval of programs in graduate medical education. The story of the background and development of these important cooperative partnerships in this important aspect of medical education and training has been presented in THE JOURNAL (September 7, page 60). The value of these committees stimulated the development about three years ago of an Internship Review Committee on which there are representatives of the American Hospital Association, the Association of American Medical Colleges, the Federation of State Medical Boards of the United States, the American Academy of General Practice, and the Council on Medical Education and Hospitals of the American Medical Association.

The remarkable success of these cooperative committee activities in the difficult task of evaluating graduate medical education and training is largely due to the sincere interest, devotion, and hard work of the physician members who give so generously of their experience and time to these activities. These busy practitioners individually devote many hours to the comprehensive study of survey reports submitted by the Council's field staff which are forwarded to them throughout the year. Such preparatory study precedes the annual meetings of the committees. The Review and Conference Committee meetings, which are held from one to three times annually for each group, consist of one-or-two-day sessions which assure group evaluation of all programs, previously individually studied, prior to taking action. From time to time, these committees find the need for special surveys of a program or programs prior to taking definitive action. In such instances, qualified *physicians* in various parts of the nation are requested to make such regional studies and submit their findings to the Committee. These eminent physicians, likewise, give freely of their knowledge, experience, and time, frequently traveling considerable distances to assist the committees, chiefs of services, and hospital administrators toward the mutual goal of strengthening graduate medical education.

Graduate medical education in general and the medical profession at large owe much to the contributions which are constantly being made by the physicians who serve so loyally on the Internship Review Committee, the Residency Review and Conference Committees, and in the conduct of special regional evaluation studies. It is this work "behind the scenes" representing the knowledge, effort, thought, and time of leaders in the various specialty fields of medicine and in general practice which is too little known and not fully appreciated. The Council on Medical Education and Hospitals is pleased to take this opportunity to express its deep appreciation to its various cooperating partners and, in particular, to the members of the profession whose cooperation and efforts have made possible the successful development of this program.

FUTURE OF THE INTERNSHIP

At the 51st Annual Congress on Medical Education and Licensure held in February, 1955, a symposium was devoted to considering the role of the internship in modern medical education.[1] It was noted that the responsibilities and duties of the intern have been increasingly delegated to student clerks on one hand and to residents on the other. There was agreement that the internship can only be defended in terms of educational value to the intern and not on the basis of service benefit to the hospital and its staff.

No unanimous conclusions were reached, but the symposium did clearly bring forth the ambiguous position of the internship as a result of the continuing development of the undergraduate clinical clerkships and graduate residency training programs. Though no final answers were provided, the long-range value of the internship as presently structured was seriously questioned.

After a period of thoughtful study, the faculty of Johns Hopkins School of Medicine has proposed a revision of its educational program.[2] One feature of the revised program is the transformation of the last medical school year into what will be the equivalent of a 12 months' rotating internship on the clinical services of the Johns Hopkins Hospital.

The many aspects of this soundly conceived educational experiment will be worthy of the attention of all physicians. Certainly the challenge that it presents to the current pattern of the internship will be of great interest and may help to elicit the firmer answers regarding the future of the internship that are needed.

NUTRITION AND PREGNANCY

Few doubt that the nutritional status and dietary habits of a mother have an effect on the outcome of her pregnancy. Most are equally willing to agree that the nutritional status of the mother prior to conception is also important, thereby expanding the area of nutrition in pregnancy to include the nutrition of the adolescent girl. This rather broad field of somewhat specialized nutrition demands the attention of the general practitioner; yet reliable information on the effective nutritional management of these patients is not always available. The Council on Foods and Nutrition, in an effort to fill this need, has enlisted the cooperation of the University of Missouri and the Boone County (Missouri) Medical Society in sponsoring a symposium on nutrition in pregnancy, to be held October 11, 1957, in Columbia, Mo.

To present the role of nutrition during pregnancy, topics discussed will include the influence of the maternal nutritional level on the fetus and infant, the metabolic and biochemical changes in normal pregnancy, the effect of the reproductive cycle on nutritional status and requirements, and dietary habits during pregnancy.

During the past 25 years it has become possible to experimentally produce a variety of congenital malformations, in the offspring of certain animals, by nutritional regimens imposed upon the mother. However, in the transition of such animal experiments to congenital malformations in humans, great caution must be exercised. In order to clarify the facts that are known, nutritional experiments as an instrument of teratological research have been included in the presentation. A panel of epidemiologic studies on nutrition in pregnancy will complete the one-day program. The symposium will subsequently be published in THE JOURNAL.

COUNCIL ON MEDICAL SERVICE

CONTROL OF FATIGUE IN OLDER PERSONS

Theodore G. Klumpp, M.D., New York

This is the seventh of a series of papers on various aspects of aging. Each paper has been prepared for the Committee on Aging by an authority in the field. When completed, the series will be published in booklet form.

Fatigue is the most prevalent limiting factor in the pursuit of an active, happy, and useful way of life by older persons. Fatigue is both a symptom in itself and a symptom complex. Generalized fatigue is a vague physical, mental, and emotional depression known to everyone but difficult to describe specifically except through synonyms such as weariness, weakness, tiredness, exhaustion, lassitude, malaise, spent, strained, overworked, and "worn-out." It is often accompanied by loss of mental acuity, impairment of memory and perception, headache, disturbances of emotional and reflex reactivity, loss of visual acuity and accommodation, functional gastrointestinal and sphincter disorders, changes in cardiac rate, rhythm, and circulatory tone, and muscular weakness and tremor. Fatigue is also accompanied by many bodily chemical and endocrine changes, reference to which is beyond the scope of this paper.

Causes of Fatigue

Fatigue is an almost universal symptom of disease. It is often the chief complaint and sometimes the only one. In view of this, the symptom should always be taken seriously and steps taken to find the underlying cause. A painstaking analysis of the patient's physical, mental, and emotional status to disclose the possibility of disease, unhygienic patterns of living, or emotional conflicts that may be the basis of or contribute to undue fatigue should be instituted. Anemia, tuberculosis, diabetes, nephritis, cardiac decompensation, and thyroid dysfunction are a few of the many specific causes of undue fatigue. It is important to keep in mind that the "small cerebral hemorrhages" of Alvarez may be followed by easy fatigability and thus bring the patient to the physician's attention. The use of tobacco and alcohol—and this need not necessarily be excessive according to ordinary criteria—should be considered as possible causes of fatigue. But the physician should guard against arbitrarily banning these and other pleasures. They may represent the solaces of a lifetime and, indeed, are more likely to have value in overcoming fatigue than otherwise. In this as in other things, a brief trial period of abstinence or curtailment may tell the story.

The importance of obesity as an etiological factor in fatigue cannot be overemphasized. Loss of weight is usually of decisive benefit, although this may not always become apparent until the weight is stabilized at a lower level. Emotional factors often play an important role in fatigability. They should not be overlooked.

In considering the significance of fatigue, it must be kept in mind that it is also a normal incident of normal living. Some individuals are unduly sensitive to their own feeling tone and are unwilling to tolerate the minor deviations from the feeling of well-being that occur to everyone. Such patients need only reassurance. However, when the pattern of fatigue has recognizably changed, or the symptom is out of proportion to the age or mode of life, or it imposes an undue limitation on ordinary activities, it should not be dismissed lightly.

In the absence of specific disease, fatigue of older persons arises principally from the following five basic causes: (1) diminution of organic reserve, particularly of the heart and circulatory system, due to loss of vascular elasticity and arteriosclerosis; (2) decline of endurance of mental and emotional effort, the basis of which is the sum of the many organic changes in the central nervous system accompanying the aging process; (3) atrophy of disuse involving all systems of the body; (4) loss of incentive, motivation, and interest; and (5) decline of endocrine activity.

In attempting to control the fatigue of older persons, the physician is confronted with the paradox of a symptom that can never be entirely cured and yet can almost always be temporarily alleviated. Fortunately, much can be done by the physician to combat fatigue, but he must be willing to devote enough time to the patient to determine which of the basic causes is predominantly responsible. There is no rule of thumb regimen that is effective in all cases, and clinical trial with periodic changes in therapy and prescribed patterns of living may be necessary. Basically, fatigue can be alleviated: (*a*) by shrinking the individual's activities to the level where the symptom largely disappears or (*b*) by measures that will tend to enhance endurance and tolerance to fatigue.

President, Winthrop Laboratories.

Members of the Committee on Aging are Drs. H. B. Mulholland, Chairman, Charlottesville, Va.; Edward L. Bortz, Philadelphia; Henry A. Holle, Austin, Texas; Wingate M. Johnson, Winston-Salem, N. C.; Theodore G. Klumpp, New York; Frederick C. Swartz, Lansing, Mich.; and Cecil Wittson, Omaha. Committee Staff: Mr. George W. Cooley, Secretary, and Mr. Herbert B. Norton, Research Assistant.

For a long time the approach to the problem of fatigue was thought to be simple. A brief history of the patient's mode of life was obtained with one objective in mind—to cut out something. It made little difference how little the individual was doing—if the patient was tired, something had to go. For instance, if the patient did nothing more than sit in a rocking chair all day long, he was no doubt advised to stop rocking and go lie down.

The enormous benefaction of rest, particularly as a therapeutic measure, cannot be questioned. But too much of a good thing, or a good thing improperly applied, may be harmful. What surgeons have learned in the practice of early ambulation we are beginning to realize has application to many medical problems and particularly to the problem of fatigue of the aged. Rest is not a universal panacea for fatigue—as thoughtful experience discloses over and over again. Many of these patients can be reduced to a vegetative existence and plied with sedatives and somnifacients and they are still tired.

What has been lost sight of is the fact that the pattern of modern civilized living, particularly in the United States, is specifically designed to avoid physical activity and stress. We have applied our enormous inventive genius and resources to the development and widespread distribution of labor-saving devices to the point where physical exertion is virtually eliminated. Young people are able to maintain their muscular and neurocirculatory tone in reasonably good condition through sports and play. As we grow older, we tend to give up these things, and, with the help of labor-saving devices, now including electric golfmobiles, we begin to suffer rapidly and too early in life from atrophy of disuse. This brings with it, among other things, a loss of functional reserve of the heart and other muscles, including those of the vascular tree. As a consequence, the slightest added stress brings on undue fatigue.

Perhaps we have lost sight of some of the following basic principles of physiology and biology that have application to this problem. 1. Functional capacities are maintained only through use. 2. Such capacities can be augmented, within limits, only through repeated stress. 3. Atrophy of disuse sets in rapidly and those capacities that are relinquished are soon lost. 4. Functional capacities decline with age, but they will decline less rapidly if they continue to be used to their fullest extent!

Prevention of Fatigue

With these thoughts in mind, it is evident that the most effective approach to the problem of fatigue of old age lies in prevention through the maintenance of an adequate neuromuscular reserve against stress. Fortunately, some degree of the same reserve can be regained at any time except where its loss is due to advanced organic disease. This may be accomplished by means of a regimen of graded exercise. The form of the exercise will depend on available resources and resourcefulness, but every effort should be made to avoid drudgery and to find some physical activity that is fun and that the patient will be inclined to continue of his own volition. Golf, swimming, hiking, bicycle riding, gardening, badminton, and tennis are among the many pleasurable forms of activity that will serve the purpose. Here, too, the rules of common sense are still applicable and too much exercise as well as too much rest can only defeat its own purpose. Along with exercise, the physician should see to it that the patient also obtains an adequate amount of sleep at night. If mental or emotional disturbances interfere with this, there is ordinarily no overriding reason why a good somnifacient should not be prescribed. A short rest at midday is of definite benefit in some cases, and almost all individuals can train themselves to sleep for half an hour if they will earnestly try.

At the same time the mental and emotional fatigue that comes at the end of a trying but sedentary day can be miraculously dispelled with a little physical exercise. It takes a particular charge of will power to undertake physical activity when fatigue is already present and all of nature seems to be crying for rest instead, or perhaps a drink. But over and over again it has been demonstrated that physical activity in such circumstances brings a degree of refreshment and renewed energy that nothing else can equal.

Undue fatigue of older persons occurs so much more commonly among those who are overweight that this circumstance warrants special emphasis. The remedy is obvious, easy to prescribe, but hard to take. A patient once told me, "What I need, doctor, is a will-power pill." In addition to dietary instructions, the importance of exercise should not be discounted, despite traditional handed down hearsay to the contrary. Its greatest value lies in its stimulating effect on endocrine activity, perhaps the thyroid in particular, and in overcoming the tendency to sleep and snooze too much—a common counterpart of obesity.

There can be little doubt that endocrine deficiencies contribute to the fatigue of old age in some individuals. This is particularly true during the menopause, and in such cases the administration of estrogens is often of benefit. Whether or not a related change takes place in men is still a matter of dispute. Nevertheless, experience suggests that small doses of testosterone are also sometimes of value in overcoming easy fatigability of older men. Thyroid extract is occasionally helpful, particularly where the basal metabolic rate is low and the serum cholesterol level elevated, but otherwise it is more often disappointing than not.

The sympathetic amines, such as methamphetamine (Desoxyephedrine) hydrochloride, phenylephrine (Neo-Synephrine) hydrochloride, and amphetamine (Benzedrine) have a potent effect in counteracting undue fatigue. As a general rule, they should not be given until other measures have failed. They are, of course, contraindicated in hypertension, coronary, and other vascular disease. Contrary to older pharmacological concepts, they are best administered in conjunction with a small dose of a sedative which permits the ergogenic effect of the amine to occur without the otherwise accompanying nervousness and sleeplessness. The sympathetic amines are particularly useful for fatigue in obese patients. Needless to say, patients receiving drugs for fatigue should be seen by the physician at regular intervals.

There is no reliable correlation between how hard a person works and degree of fatigue. If anything, fatigue of older persons is seen more commonly among those patients who do not have enough to do. Too often they feel that their life work is done and their fatigue has its origin in boredom and loss of incentive and interest. Over and over again, when a crisis arises or something of deep interest comes along, these individuals miraculously lose their fatigue.

It is, of course, difficult for a physician to prescribe an interest where there is no interest. Unfortunately "make work" programs often fail because they are undertaken half-heartedly and the necessary compelling motivation is lacking. However, this should not serve as a deterrent, because a new and absorbing interest is the only real salvation for some of these patients. When they find it, as some do, their symptoms disappear and they are given a new lease on life.

COUNCIL ON NATIONAL DEFENSE

ARMED FORCES PROGRAM FOR RESIDENCY DEFERMENT

The following report is authorized for publication by the Council on National Defense as a matter of interest to recent medical graduates who have an obligation for military service.

Frank W. Barton, *Secretary.*

Established in 1954 with the cooperation of the Selective Service System, the Department of Defense inaugurated its Armed Forces Reserve Medical Officer Commissioning and Residency Consideration Program as a method to fulfill needed medical specialty requirements for the armed forces. Each year a certain number of young men are selected for recommendation for deferment in order to obtain residency training in specialties needed by the military departments. The number selected each year is based upon the projected need for specialists.

In July of each year, all interns with a liability for military service are mailed an Informational Bulletin and application blank for participation in the program. Selections for deferment for residency training are made in the latter part of September, and all participants are allocated to the three military departments for the purpose of obtaining a commission.

In the 1957 program, about 2,800 participating residents will be authorized to be in a deferred status. About 1,000 will start their first year of training and the remainder will be in their second, third, or fourth year. It is expected that about 1,000 interns will be recommended for deferment each year.

In the programs for 1956 graduates, there were 3,667 participants. Of the 2,203 who requested deferment, 1,200 were selected. There were 1,464 interns who requested active duty immediately following internship. All who requested will be brought to duty during July-September, 1957.

Selections for recommendation for deferment will be made in the specialties as indicated in the table.

Number of Selections for Recommendation for Deferment, by Specialty

Specialty	Army	Navy	Air Force	Total
Anesthesiology	20	16	7	43
Dermatology and syphilology	8	0*	0*	8
General practice	0	18	58	76
Internal medicine	65	72	12	149
Neurology	4	0*	12	16
Neurosurgery	2	0*	0*	2
Obstetrics and gynecology	50	12	18	80
Ophthalmology	25	12	0*	37
Occupational medicine	3	0	10	13

Urology	6	12	0	18
Total	400	400	200	1,100†

* Requirements in this specialty filled by training programs for career officers.

† An overselection of 20% will be made to allow for drop outs.

The intern and residency training programs continue to be the main source of procurement for career medical officers. Recently, the Department of Defense issued a nine-page Informational Bulletin outlining the program and explaining how the program applies to 1957 medical graduates. It contains a number of typical questions on the program, with answers. Copies of the Informational Bulletin may be obtained by writing the Assistant Secretary of Defense (Health and Medical), Department of Defense, Washington 25, D. C.

MEDICINE AND THE LAW

ANALYSIS OF PROFESSIONAL LIABILITY CLAIMS AND SUITS

This is the 16th in a series of articles dealing with medical professional liability. An editorial (page 360) and a chronological résumé (page 364) appeared in THE JOURNAL, *Feb. 2. The preceding articles in this series have been published weekly in* THE JOURNAL *from Feb. 9, 1957, to April 6, and since then intermittently.*—ED.

A study of the subject of medical professional liability would not be complete without a review of the experience of physicians who have been a party to an actual claim or suit. In an effort to collect detailed information in this regard, questionnaires were mailed in July, 1956, to a scientifically selected sample of 7,577 physicians consisting of roughly 5% of the members of the American Medical Association. These questionnaires solicited opinions on various aspects of medical professional liability and also inquired whether a professional liability claim or suit had ever been brought against the physician.

Two follow-up questionnaires were sent to those who had not replied. When the second follow-up was sent, a post card was enclosed which asked the physician to check one of the following: "A professional liability claim or suit has *never* been filed against me; A professional liability claim *has* been filed against me; or, A professional liability suit *has* been filed against me." Physicians were asked to return the post card if, for some reason, they would not return the questionnaire.

Counting the questionnaires and post cards, an 83.0% return was received. From the total returns it was possible to ascertain that 12.8% of the physicians responding had been involved in a claim or suit and 87.2% had not.

The total number of usable questionnaires constituted 71.2% of the original sample. The report analyzing these questionnaires appeared in the Aug. 3, 1957, issue of THE JOURNAL in the section Medicine and the Law.

As the second step in this phase of the survey, a completely different questionnaire—a request for a case history—was sent to the 748 physicians who indicated that they had been involved in a medical professional liability claim or suit. If, on the first questionnaire, the physician indicated he had multiple claims, one questionnaire was sent to him for each claim or suit reported.

A total of 661 usable case histories were received and are the basis of the following analysis. The data and percentages reported are based on total claims, not total physicians. Every claim involved a physician, but one physician may have been involved in more than one claim. The results are also qualified by the fact that the case history questionnaires were sent to physicians who indicated on the first questionnaire that they were involved in a claim or suit. These claims, therefore, or the physicians who had them, were not selected from a random sample but constitute a follow-up of a select group.

A further qualification is the fact that this analysis constitutes the experience of a group of living physicians. This point becomes important in a time series analysis. For example, a tabulation of the year in which the claim was brought reflects the experience of physicians living today, not the total or even a sample of the total number of claims brought against physicians in that period. Thus, the farther away the period involved is from the present, the less representative the sample is of that period because of the natural attrition of the physician population.

In the following tables we have reported the facts as they have been given by physicians who had a professional liability claim or suit brought against them. In presenting these 661 case histories every effort has been made to abstain from interpretation and editorial comment.

The geographical regions referred to in some of the tables are those established by the United States Department of Commerce. By way of explanation, the New England states include Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut. The Middle Atlantic states include New York, New Jersey, and Pennsylvania. The South Atlantic states include Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida. The East North Central states include Ohio, Indiana, Illinois, Michigan, and Wisconsin. The East South Central states include Kentucky, Tennessee, Alabama, and Mississippi. The West North Central states include Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas. The West South Central states include Arkansas, Louisiana, Oklahoma, and Texas. The Mountain states include Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, and Nevada. The Pacific states include Washington, Oregon, and California.

Time Claim Was Brought—Ten-Year Periods

A review was made of the "case histories" to determine, by geographical area, the percentage of claims brought in each 10-year period beginning from 1900 to the present. Again, caution is urged in interpreting these figures, for they do not mean that the increase in all professional liability claims or suits is as marked in the period from 1939 to present as one might assume by a hurried reference to table 1. The figures refer only to claims against living physicians who returned the professional liability questionnaire.

TABLE 1.—*Percentage of Claims Filed by Time and Region*

	1900-1909	1910-1919	1920-1929	1930-1939	1940-1949	1950-1957	Unknown

Pacific	2.5	1.9	17.3	19.8	19.8	19.8	7.4	4.3	3.1	...	1.2	3.1
United States	1.5%	1.5%	17.1%	19.1%	15.9%	16.0%	9.8%	8.3%	4.2%	2.0%	2.8%	1.8%

Years in Practice at Time of Alleged Incident

One of the questions on the questionnaire was "How long had you been in practice at the time of the alleged incident?" The answers received have been included in table 2, shown in percentages and broken down by five-year periods. The median years in practice vary from 8.0 in the Mountain states to 16.6 in the Middle Atlantic states. The median for the United States as a whole is 13.4 years.

Nature of Practice and Place Alleged Act Occurred

The physicians involved in the reported claims and suits were for the most part engaged in active private practice. The percentage of claims in the six specific categories most frequently mentioned is shown, by geographical area, in table 3.

Inasmuch as most of the more serious medical and surgical procedures are performed in hospitals it was not surprising to find that the highest percentage of the acts of negligence alleged in the cases reported occurred in hospitals. The answers to the questionnaires revealed that the alleged negligent acts occurred in hospitals, 67.2%; doctor's office, 23.9%; patient's home, 6.3%; miscellaneous (place of employment, doctor's home, jail, etc), 2.0%; and place not stated, 0.6%.

Type of Practice Involved in Reported Claims and Suits

In the majority of instances the claims and suits reported were against physicians engaged in full-time specialty practice. The figures further reflect, however, that the alleged incident on which the claim or suit was based occurred to physicians who were not board-certified. Table 4 shows, by geographical area, the percentage of claims involving physicians by type of practice and the percentage of claims by board-certified physicians. It cannot be taken for granted from these figures that the incident on which the action was based occurred in the field in which the physician was certified.

A further analysis of the information supplied in this regard revealed that the alleged incidents occurred most frequently in the following fields of medical practice: surgery, 30.9%; medicine, 20.0%; orthopedics (including surgery), 19.7%; obstetrics and gynecology, 12.5%; neurology and psychiatry, anesthesiology, radiology and others, 16.9%. No significant variation from nationwide figures was evident in any geographical area.

TABLE 3.—*Nature of Practice—Percentages by Geographical Area*

	Active Private Practice	Intern, Resident, Employee of Hospital	Industry	Local Government	Armed Forces	University	Other
New England	97.1%	2.9%	.. %	...%	...%	...%	...%
Middle Atlantic	97.1	2.2	0.7	...	...	...	...
South Atlantic	85.5	11.3	1.6	...	1.6	...	...
East North Central	94.0	3.4	0.9	1.7	...	...	...
East South Central	94.1	5.9	...	...	...	...	...
West North Central	90.9	4.6	3.0	...	...	1.5	...
West South Central	93.8	3.1	...	...	...	...	3.1
Mountain	91.0	3.0	...	...	...	3.0	3.0
Pacific	91.4	6.2	...	1.2	1.2	...	...
United States	92.8%	4.7%	0.8%	0.6%	0.5%	0.3%	0.3%

Nature of Alleged Negligent Act

The case histories disclosed the percentage breakdown shown in table 5 with respect to the alleged bases for the claims or suits reported.

TABLE 4.—*Type of Medical Practice—Physician Board-Certified*

	Full-time Specialist	General Practitioner	Part-time Specialist	Intern or Resident	Other or Unspecified	Board-Certified	
						Yes	No
New England	47.1%	38.2%	11.8%	2.0%	...%	29.4%	70.6%

Persons Performing Negligent Act and Those Joined in Claim or Suit

In approximately three-fourths of the cases reported, the alleged negligent act was performed by the reporting physician. Table 6 indicates the profession of individuals who allegedly performed the negligent act in the remaining cases. The second column of the table shows the percentage of cases with more than one defendant and the types of joint-defendants involved.

Secondary Causes of Claims or Suits

In a majority of the case histories reported it was indicated that some factor in addition to the alleged negligent act prompted the individual to file a claim or suit. The enumeration of these factors in table 7 discloses that these secondary causes may be grouped in four categories: 1. Factors under the control of the medical profession. In this group are to be found 27.3% of the secondary causes. 2. Pressure or influence exerted on the claimant by outsiders. In this group are to be found 22.6% of the secondary causes. 3. The patient himself as a producing factor. In this group are to be found 24.6% of the secondary causes. 4. The fourth factor is the miscellaneous group, which accounts for 25.5% of the secondary causes.

TABLE 5.—*Primary Bases for Claims or Suits*

Poor operative result	24.7%
Poor medical result	19.3
Error in diagnosis	10.1
Foreign bodies left in patient	8.6
Burns	7.9
Assault, lack of consent	4.0
Abandonment	2.8
Error in prescription	2.6
Poor neuropsychiatric results	2.2
Improper commitment of *incompetents*	2.1
Faulty equipment	1.9
Sterilization procedures	1.9
Blood *transfusion accidents*	0.9
Miscellaneous or no answer	11.0

This information indicates that it is within the power of physicians themselves to remove a considerable percentage of secondary precipitating causes for filing claims or bringing suits. This may be accomplished by refraining from criticism of the care and treatment accorded by other physicians and by utilizing discretion and tact in billing and collection procedures. This latter fact is substantiated by the significant number of responses grouped under "miscellaneous" which indicate that pressure in collecting the physician's bill was a precipitating cause for the professional liability claim or suit. Claims may be reduced by handling ancillary medical conditions personally and promptly or by referring patients to another physician. Room for improvement is also possible by taking care in maintaining proper records and inviting consultation when alcohol or drug addicts are involved.

TABLE 6.—*Persons Involved in Negligent Act and Claims or Suits*

	Negligent Act Performed by	Joined in Claim or Suit
Reporting physician	72.5%	...%
Another physician	11.2	47.4
Nurse	6.8	8.7
Intern or resident	3.2	7.8
Technician	2.0	1.8
Anesthetist (not M.D.)	2.0	3.0
Pharmacist	0.3	1.3
Hospital	...	28.7
Miscellaneous or unknown	2.0	1.3

TABLE 7.—*Secondary Bases for Claims or Suits*

Under Physician's Control	
Careless comment about another physician	25.2%
Patient had another disease or disability which progressed badly	2.1
Outside Influence	
Action prompted by attorney	15.4
Action prompted by *relative*	7.2
Patient a Factor	
Claim brought for financial profit	13.8
Mental disability	7.9
Alcohol or narcotic addict	2.9
Miscellaneous, Not Possible to Classify	25.5

Information Concerning Claimants

In submitting case histories, physicians were asked to supply information concerning the sex, age, and occupation of the person bringing the claim or suit. With respect to age it appears that the majority of claimants are between 29 and 40. The median age for the United States as a whole is 34.4 years. The median age by geographical area ranges from 23.8 years in the East South Central states to 40.4 years in the Pacific states. With respect to the sex of the claimant, the questionnaires indicated that nationwide 55.1% of the claims and suits were filed by females and 43.1% by males; in the remaining cases (1.8%) the sex of the claimant was not stated.

Table 8 indicates a percentage breakdown, by geographical area, of the occupations of the persons filing the claims and suits reported.

Attempts at Settlements and Reasons

It appears that some of the claimants in the reported claims and suits attempted for a number and variety of reasons to negotiate a settlement.

TABLE 8.—*Occupation of Claimants*

	Housewives	Laborers and Farmers	Craftsmen, Foremen, Etc.	Service Workers, Including Protective and Domestic	Clerical Workers	Sales Workers	Retired	Semiprofessional Worker	Professional Worker	Proprietors, Managers, Officials	No Answer and Unemployed
New England	32.4%	5.9%	8.8%	2.9%	11.8%	2.9%	5.9%	...%	5.9%	...%	23.5%
Middle Atlantic	30.4	6.5	9.4	3.6	2.2	5.1	3.6	3.6	2.2	2.2	31.2
South Atlantic	30.6	9.7	8.0	9.7	6.5	3.2	1.6	...	6.5	...	24.2
East North Central	38.5	12.8	6.8	6.8	3.4	4.3	2.6	1.7	1.7	1.7	19.7
East South Central	41.2	...	5.9	...	5.9	...	...	5.9	...	...	41.1
West North Central	28.8	18.2	9.1	7.6	1.5	7.6	3.0	4.5	1.5	1.5	16.7
West South Central	40.6	6.3	15.6	6.3	3.1	...	3.1	3.1	...	...	21.9
Mountain	39.4	6.1	12.1	...	3.0	3.0	3.0	...	6.1	...	27.3
Pacific	29.0	10.5	6.8	4.9	5.6	3.7	3.1	4.9	1.2	3.7	26.6
United States	32.7%	9.8%	8.5%	5.3%	4.3%	4.1%	3.0%	3.0%	2.4%	1.8%	25.1%

A much smaller percentage of the physician defendants were apparently interested in a settlement. For the United States as a whole, an attempt was made by the physician to settle the case out of court in 19.5% of the cases. In 73.5% of the cases no attempt was made by the physician to settle and in 7% no answer was given. The few physicians who did seek settlement reported the reasons shown in table 9.

TABLE 9.—*Reasons Physicians Attempted Settlement*

Advice of attorney	26.7%
To avoid unfavorable publicity	24.1
Responsibility apparent	13.8
Cheaper than court costs or to avoid appearance in court	11.2
To settle for smaller amount than verdict might bring	7.8
To save time	4.3
Avoid strain of litigation because of poor health	2.6
Miscellaneous	9.5

Disposition of Claim or Suit

A significant percentage of the claims reported became the basis for a suit. Of the claims reported, 43.1% developed into a suit; 32.4% of the claims were settled or compromised by a money payment; 17.1% were dropped; and the remainder or 7.4% of the claims were still pending or their status was unknown. Information with respect to the status and disposition of the suits reported is shown in table 10. It was also reported that claimants obtained a money settlement or an award, following a suit, most frequently in cases involving obstetrics and gynecology, and anesthesiology.

Figures concerning the disposition of settled claims and suits indicate that 53.1% of the cases were compromised or settled or decided in favor of the claimant. In cases finally decided by the courts only 18.7% were decided for the claimant. The basis for this percentage does not include cases which are pending or those dropped or compromised.

Professional Liability Insurance Status of Physicians

Case histories reflect that nationwide 93.2% of the physicians responding were covered by medical professional liability insurance at the time of the alleged incident, on which the reported claim or suit, was based. The next information requested was whether, as a result of the claim or suit, the physician experienced any difficulty in obtaining or renewing his professional liability insurance coverage. This information is reflected in table 11, by geographical area.

TABLE 10.—*Status or Disposition of Suits Reported—Percentage Breakdown*

	Pending	Decided for Claimant	Decided Against Claimant	Dropped	Compromised
New England	21.4%	...%	35.7%	...%	42.9%
Middle Atlantic	34.0	8.9	21.4	14.3	21.4
South Atlantic	12.1	6.1	48.5	12.1	21.2
East North Central	15.7	11.8	43.1	11.8	17.6
East South Central	...	...	66.7	33.3	...
West North Central	18.2	13.6	45.5	4.5	18.2
West South Central	35.3	5.9	35.3	11.8	11.8
Mountain	10.0	20.0	50.0	20.0	...
Pacific	9.2	10.5	48.7	10.5	21.1
United States	18.2%	9.5%	41.1%	11.6%	19.6%

Conclusions

The tables naturally promote speculation. For instance from these histories it is possible to picture the composite claimant as 34.4 years old, a housewife, who was, most probably, dissatisfied with an allegedly poor operative result. The national com-

MEDICAL NEWS

ILLINOIS

State Anesthesiologists Meeting.—The Illinois Society of Anesthesiologists will meet Oct. 5 in the Beaubian Room of the Prudential Building, Chicago. A social hour will be held at 5 p. m., with dinner at 6 p. m. and the program beginning at 7:30 p. m. Dr. Richard Foregger, director, department of anesthesiology, Marquette University School of Medicine, Milwaukee, Wis., will present "The Respiratory Valve." A business meeting will follow.

Chicago

Appoint Director of Medical Education.—Dr. Robert E. Slayton has been appointed director of medical education at St. Luke's Hospital. His duties are to strengthen and direct the educational program for the hospital intern and resident staff. Dr. Slayton previously was associated with St. Luke's as a resident in medicine from 1951 to 1953; he was a fellow in medicine at the Joslin Clinic, Boston, 1953-1954, and later became a lieutenant in the United States Navy.

Medical History Meeting.—An open meeting of the Society of Medical History of Chicago will be held at the Institute of Medicine Oct. 9 at 8 p. m. Program topics and speakers follow: "Concepts of Psychic Functions—East and West," Ilza Veith, Ph.D., associate professor of the history of medicine, University of Chicago; and "Franklin D. Roosevelt, the Common Cold, and American History," Dr. Noah D. Fabricant, clinical assistant professor of otolaryngology, University of Illinois College of Medicine.

Heart-in-Industry Conference.—The Chicago Heart Association, the Chicago Association of Commerce and Industry, and the Central States Society of Industrial Medicine and Surgery announce the fifth heart-in-industry conference, a memorial to Gustav Freund II, to be held Oct. 11 at the Morrison Hotel. The theme, "Living with Your Job," will be discussed by Philip M. Hauser, Ph.D., University of Chicago; Dr. Benjamin Boshes, Northwestern University; Dr. Roy R. Grinker, Michael Reese Hospital; Dr. Allen McLean, International Business Machines Corporation; Mr. S. DeWitt Clough, Chicago Heart Association; Dr. Edward C. Holmblad, Industrial Medicine Association; Mr. William F. Brown, U. S. Steel Corporation; and Mr. Norman G. Brodie, Ford Motor Company. Luncheon speakers include Dr. Robert Collier Page, consultant in manpower development, New York City; and Mr. Oscar Mayer, chairman of the board, Oscar Mayer and Company. For information write the Chicago Association of Commerce and Industry, 1 North La Salle, Chicago 2.

MARYLAND

Personal.—The Royal Medico-Psychological Association of Great Britain has invited Dr. Leo Kanner, chief, children's psychiatric service, Johns Hopkins Hospital, Baltimore, to deliver the annual Maudsley Lecture in London, England, in November, 1958. Dr. Kanner will be the third psychiatrist for the West and the first child psychiatrist to be so honored.

General Practice Meeting.—The ninth annual scientific assembly of the Maryland Academy of General Practice will be held at the Tidewater Inn, Easton, Oct. 9-10. Nine category I credit hours will be given for attendance. The program includes the following topics by out-of-state speakers:

Toxemias of Pregnancy, Dr. Washington C. Winn, professor of clinical obstetrics, Medical College of Virginia, Richmond.

Approach to Fluid Balance and Blood Electrolytes, Dr. R. V. Kron, medical department, Mead Johnson Company, Evansville, Ind.

Vascular Disease in the Diabetic, Dr. Howard F. Root, physician-in-chief, Deaconess Hospital, Boston.

Surgery of Acquired Valvular Heart Disease and Results, Dr. Robert P. Glover, clinical professor of thoracic surgery, Hahnemann Medical College and Hospital, Philadelphia.

TB Case Finding, Diagnosis and Teatment for the General Practitioner, Dr. Julius Wilson, director of medical education, National Tuberculosis Association.

A panel discussion, "Diagnosis of Heart Disease," is scheduled. The banquet will be held Oct. 9. A ladies' program has been arranged. For information write the Maryland Academy of General Practice, 3722 Greenmount Ave., Baltimore 18, Md.

MASSACHUSETTS

Dr. Dana Honored.—Dr. George W. Dana, of Wellesley Hills, medical staff director of Boston's New England Center Hospital was named the first recipient of the Medical Achievement Travel award, presented by the Purdue Frederick Company of New York, pharmaceutical firm. The award, "for his distinguished contributions to postgraduate

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

medical education," was made at a reception at the Barbizon Plaza Hotel in New York City. In announcing the award, Benjamin Schneider, president of the Purdue Frederick Company, said, ". . . The highlight of Dr. Dana's projected trip abroad will be a series of visits to medical meetings, seminars, teaching centers, hospitals and research facilities in England, France, Italy, and Sweden."

Personal.—Dr. James B. Dealy Jr., Newton, has been appointed radiologist-in-chief at Boston's Peter Bent Brigham Hospital, succeeding Dr. Merrill C. Sosman, who is currently on a visiting and lecture tour of Australia.——Dr. Patrick F. Butler, Boston, fellow emeritus of the American College of Radiology, was presented by Holy Cross College with an honorary doctor of science degree at recent commencement exercises in Worcester.——Dr. John J. Lorentz, of Methuen, has been appointed physician-in-charge of the Boston Dispensary Rehabilitation Institute and assistant professor of physical medicine and rehabilitation at Tufts University School of Medicine. Both are units of the New England Medical Center. Dr. Lorentz formerly was assistant medical director of the Bay State Medical Rehabilitation Clinic and the department of physical medicine of Massachusets General Hospital.

NEW YORK

Appoint Hospital Director.—Dr. George L. Warner, assistant director of Marcy State Hospital, has been appointed director of Craig Colony, state hospital for epileptics in Sonyea, Livingston County, succeeding Dr. William C. Johnston, who has returned to his former post in the department of correction. Dr. Warner has been at Marcy State Hospital for 14 years, serving as assistant director and acting director. He began his career with the state in 1923 at Marcy State Hospital, progressing through successive grades until his appointment as clinical director at Matteawan State Hospital for the Criminally Insane in 1931. In 1941 he became clinical director at Utica State Hospital, and two years later he transferred to Marcy. He is a diplomate of the American Board of Psychiatry and is currently president of the Mohawk Valley Neuropsychiatric Society.

Centers for Retarded Children.—A grant of $45,000 to establish the Buffalo Diagnostic and Counselling Study Center for Mentally Retarded Children has been announced. This center will be an integral part of the rehabilitation center of the Children's Hospital and Crippled Children's Guild. The Interdepartmental Health Resources Board, which has the responsibility of the initiation and development of health programs of interdepartmental concern, is promoting such centers. The Buffalo center is the first major clinic of its type to be established in the Upstate New York area. Complete evaluation, diagnosis, and treatment will be offered to children suspected of being or known to be mentally retarded. In addition to a complete medical and psychological diagnosis, an estimate will be made of their capabilities, with emphasis laid upon what the child may be able to do rather than on his disabilities. The center will also act as a consultation service to private physicians, social agencies, and schools and will cooperate with all agencies serving the mentally retarded child. Other features of the program will be teaching of undergraduate and postgraduate medical students, graduate physicians, nurses, psychologists, and social workers in modern techniques of treatment, evaluation, and diagnosis of mental retardation.

New York City

Public Health Positions Available.—The City of New York is seeking applicants to serve as senior public health physicians (District Health Administration) with its Department of Health. Physicians in these positions administer the community health services of a large health district, a health district with unusual or specialized problems, or a special public health program. New York City is divided into 30 public health districts. The larger districts are equivalent to cities of over 300,000 population. Candidates must be graduates of a school of medicine and must have one year of formal appointment as an intern in an approved general hospital. In addition, they must have a master's degree in public health and three years of full-time paid experience. Candidates who hold a licence to practice medicine in states other than New York will be required to obtain a New York State license by the end of the third month of their employment. The salary range for senior public health physicians is $11,200 to $13,600 a year. If conditions warrant, the Civil Service Commission may examine for these positions in such locations outside New York City as Boston, Chicago, Cleveland, and Washington, D. C. For information write Mr. Arnold de Mille, Director of Recruitment, The City of New York, Department of Personnel, 299 Broadway, New York 7, N. Y.

GENERAL

Undergraduate Essay Contest.—The American College of Chest Physicians announces the 1958 prize essay contest offering three cash awards: first prize, $500; second prize, $300; and third prize, $200. The contest is open to undergraduate medical students throughout the world. Essays may be written on any phase of the diagnosis and treatment of chest diseases (heart and/or lung). The contest closes April 15, 1958. For information write the American College of Chest Physicians, 112 E. Chestnut St., Chicago 11, Ill.

Winners of the 1957 contest and their subjects are as follows:

Henry Buchwald, Columbia University College of Physicians and Surgeons, New York City, "The Surgical Treatment of Coronary Heart Disease."

James T. Post, University of California Medical School, San Francisco, "The Incidence of Pulmonary Tumors in Mice Exposed to Aerosols of Therapeutic Agents."

Stephen A. Kieffer, University of Minnesota Medical School, Minneapolis, "A Trial Septal Defect: An Evaluation of Surgical Closure."

Anesthesiologists Meet in Los Angeles.—The annual meeting of the American Society of Anesthesiologists will be held Oct. 14-18 at the Hotel Statler, Los Angeles. An address will be given by Major General Paul I. Robinson, M. C., executive director, Office for Dependents' Medical Care, Washington, D. C., on Oct. 15. The following panel discussions are planned: Muscle Relaxants: The Changing Picture; Pediatric Care; Effectiveness of Mechanical Ventilators; Patient with Cardiac Disease as a Surgical Risk; Anesthesia and the Midbrain; Instrumentation Applicable to the Teaching and Clinical Practice of Anesthesiology; and Office Practice of Anesthesiology. Foreign speakers and their topics include Dr. Edith Simandl, Second Surgical University Clinic, Vienna, Austria, "Experience with Stellate Ganglion Block and Paravertebral Sympathetic Block Treatment in Sudeck's Disease," and Dr. Joachim Bark, Tubingen University, Tubingen, Germany, "Limiting Factors in Resuscitation." Motion picture sessions and exhibits are planned. A dinner-dance is scheduled for Oct. 17. For information write the American Society of Anesthesiologists, Inc., 188 W. Randolph St., Chicago 1.

Southwestern Medical Association Meets in El Paso.—The annual meeting of the Southwestern Medical Association will be held Oct. 9-11, with headquarters at the Hotel Paso del Norte, El Paso, Texas. Addresses will be given by Dr. Robert F. Thompson, president of the El Paso County Medical Society, and Dr. Celso C. Stapp, president of the association. Following are the guest speakers: Dr. William Parson, University of Virginia School of Medicine, Charlottesville; Dr. Oscar Creech Jr., Tulane University of Louisiana School of Medicine, New Orleans; Dr. E. E. Muirhead, Southwestern Medical School of the University of Texas, Dallas; Dr. Frederick C. Bost, president, American Academy of Orthopedic Surgeons; Dr. J. S. De Tar, past-president, American Academy of General Practice; Dr. Robert H. Hingson, Western Reserve University, Cleveland; Dr. Howard P. House, University of Southern California School of Medicine, Los Angeles; Dr. Phillip Thygeson, University of California School of Medicine, San Francisco; and Dr. Edward A. Banner, Mayo Clinic, Rochester, Minn. Scientific and technical exhibits are planned. The banquet will be held Oct. 11. A ladies' program has been arranged. Registration fee is $15. For information write Southwestern Medicine, Suite 700 Electric Building, El Paso, Texas.

Fellowships in Allergy.—The American Foundation for Allergic Diseases has announced the availability of postdoctoral fellowships in research and clinical allergy for two years each, with stipends as follows: first year, $4,500; second year, $4,750; laboratory and travel expenses for two-year period, $750. Candidates must be graduates of approved medical schools and must have completed one or two years of the graduate training required as a preliminary to certification by the Boards of Internal Medicine or Pediatrics; they are to devide their time between research and clinical training, and in the second year 10% or 15% of a candidate's time might be devoted to teaching. The respective institutions have taken the necessary steps to have this training credited toward the subspecialty in allergy by the Board of Internal Medicine and the Board of Pediatrics.

Requests for applications should be sent directly to one of the following, in whose field the candidate would like to work: Dr. Colin M. MacLeod, professor of Research Medicine, University of Pennsylvania, 820 Maloney Clinic, 36th and Spruce Streets, Philadelphia 4, Pa., or Dr. Herman N. Eisen, Professor of Medicine (Dermatology), Washington University School of Medicine, 600 South Kingshighway, Saint Louis 10, Mo. Applications should be filed no later than Dec. 15. Notification will be mailed to successful candiates by Feb. 1, 1958.

Military Surgeons Meeting in Washington, D. C.—The 64th annual convention of the Association of Military Surgeons of the United States will be held Oct. 28-30 at the Hotel Statler, Washington, D. C. Theme for the convention is "Professional Excellence—The Criterion of Military Medicine." The presidential address will be given by Col. Amos Koontz, M. C., National Guard, Maryland. Topics for the general sessions include disaster medicine and the challenge of peace in the Pacific. The following panel discussions will be held:

Medical Education in the Federal Services, moderated by Dr. Frank B. Berry, assistant secretary of defense (health and medical).

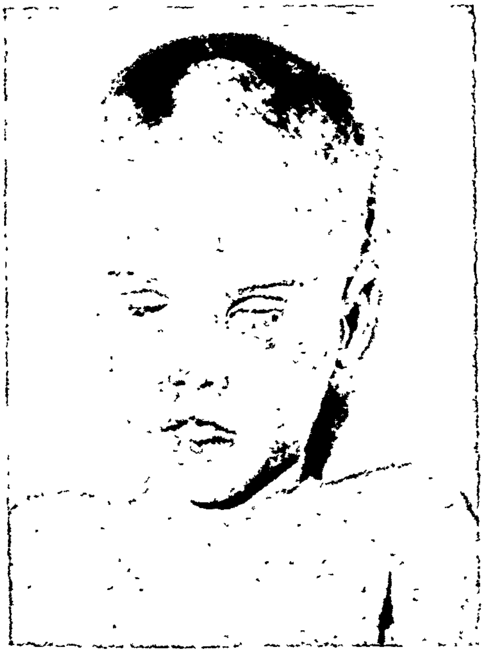
Surgery of the Large Intestine, with Brig. General Sam F. Seeley, M. C., U. S. Army, chief, professional division, Office of the Surgeon General, Washington, D. C., presiding.

Management of Patients with Coronary Artery Disease, a joint medical and surgical panel.

Training of Enlisted Medical Technicians, moderated by Dr. Russell A. Nelson, director, Johns Hopkins Hospital, Baltimore.

Medical motion pictures will be shown throughout the convention. An international luncheon ceremony will be held Oct. 29. Entertainment includes a U. S. Army Band Concert, Oct. 29, and a dinner-dance, Oct. 30. Scientific exhibits and a special ladies' program are planned. For information write the Association of Military Surgeons in the United States, Suite 718, New Medical Building, 1726 Eye St., N. W., Washington 6, D. C.

Seek Identity of Slain Boy.—Police Commissioner Thomas J. Gibbons of Philadelphia believes that some physician in the United States might help solve a brutal murder case that has been baffling detectives of that city for more than seven months. Last Feb. 25 the nude body of a white boy 4 or 5 years old, wrapped in a cheap blanket, was found in a cardboard carton in an isolated section of Philadelphia. Multiple bruises indicated that death from head injuries occurred violently between 3 and 14 days before discovery of the body. The victim was 40½ in. tall, weighed 30 lbs., had crudely cut brown hair, blue eyes, a full set of baby teeth, neatly clipped finger and toe nails, and a small L-shaped scar under his chin.



Face of the dead child.

Dr. Joseph Spelman, medical examiner for Philadelphia, reports there also was a half-inch long crescentic scar on the righ side of the neck, and a short, well-healed hairline scar overlying the third interspace one and one-half inches to the left of the anterior midline. There were two small old hairline healed scars in the right femoral and right inguinal triangles which may represent surgical incisions, according to Dr. Spelman.

"We feel that the child might readily be recognized by a physician who has treated him," wrote Police Commissioner Gibbons in a letter to the American Medical Association. "It is possible that he was a resident of the Philadelphia area. However, the case has been so widely publicized here that this now seems doubtful. My purpose in writing is to appeal to you for assistance in publicizing this mysterious case nationally to the medical profession."

Physicians who may be able to supply a clue to the dead boy's identity are asked to notify Philadelphia detective headquarters (telephone MUnicipal 6-9700) or their local police department.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Pacific Coast Fertility Society.—The seventh annual meeting of the Pacific Coast Fertility Society will be held Nov. 7-10 at the El Mirador Hotel in Palm Springs, Calif. Scientific sessions will be devoted to presentations related to new advances in the management of clinical infertility. The meeting is open to all physicians and research workers. Registration fee is $10. There is no fee for interns, residents, or armed services medical officers. Program chairman is Dr. Albert L. Banks, 707 Broadway, Seattle. Advance registration may be made by writing to Dr. Edward T. Tyler, Secretary-Treasurer, 921 Westwood Blvd., Los Angeles 24, Calif.

Midwest Physicians Meeting.—The midwest regional meeting of the American College of Physicians will be held Oct. 12 at Lincoln Hall, University of Illinois, Urbana-Champaign. A total of 21 papers are scheduled for presentation, including "Reversible Hypertension and Unilateral Renal Artery Disease," by Dr. Derek D. Gellman, Berkeley Fellow, Middlesex Hospital, London, England. Dr. Richard A. Kern, president, American College of Physicians, will speak on "Some Personal Observations in the Near and Middle East" at the dinner at the Urbana-Lincoln Hotel. A program of ladies' entertainment has been arranged. For information write Dr. B. Smith Hopkins Jr., 602 W. University Ave., Urbana, Illinois.

Audiology and Speech Fellowships.—Establishment of two fellowships in audiology and speech at Northwestern University, Evanston, Ill., has been announced by the American Hearing Society, its member agency, the St. Paul Hearing Society, and the university. The training program will be geared to preparing qualified persons for work in local hearing societies. The fellowships, made possible by a bequest from the Myers Foundation of St. Paul, Minn., are to be known as the Reine Humbird Myers Fellowships. Each fellowship will pay $3,000 a year for two years. For information write Mr. Crayton Walder, executive director, American Hearing Society, 1800 H St., N. W., Washington 9, D. C., or to Raymond Carhart, Ph.D., School of Speech, Northwestern University, Evanston, Ill.

CANADA

University Survey of General Medical Practice.—A study of general medical practice in Canada is being carried out by the School of Hygiene of the University of Toronto with aid from a Rockefeller Foundation grant of about $115,500 available over a two-year period.

The study, already begun, is employing many of the techniques, such as personal interviews, direct observation of the work of the participating physicians, and statistical methods, developed in a similar study at the University of North Carolina, Chapel Hill. Because of great variations in population density, economic prosperity, medical practice habits, and methods of payment for medical care in different parts of Canada, however, the University of Toronto study will be conducted on a Dominion-wide basis. The program has been divided into stages, the first of which, limited to the Province of Ontario, is already well advanced.

In its survey the university examines the type and volume of illness treated by general medical practitioners. The university also intends to study the types of practice found in several areas in an effort to determine the type of family doctor needed in the diverse economic and geographic regions of Canada. The project has the backing of the Canadian Medical Association and Canadian College of General Practice, and the financial support of the Canadian Department of Public Health and the Canadian Life Insurance Officers' Association.

LATIN AMERICA

Yellow Fever Virus in Panama.—The Government of Panama has informed the Pan American Sanitary Bureau, World Health Organization, that the virus of yellow fever has been isolated from a batch of *Haemagogus lucifer* mosquitoes captured in Peñas Balces, Province of Colón. This locality is near the Trans-Isthmian Highway, 20 miles southeast of the city of Colón.

FOREIGN

Dr. Guleke Honored.—The International College of Surgeons has conferred upon Prof. Dr. Nicolai Guleke, professor emeritus of the University of Jena, Germany, and former professor of the Surgical University Clinic, Marburg, Germany, the designation of "Master Surgeon." Only five others have been given this distinction in the College's 22 years of existence. Prof. Guleke developed operations for rectal cancer, joint diseases, and tumors within the chest. The honor was announced at ceremonies which climaxed the recent congress of the U. S. and Canadian Sections of the college.

European Federation of Surgeons.—Two meetings of the newly formed European Federation, International College of Surgeons, have been announced. One will be held in Vienna Oct. 18-20 and the other during the World's Fair in Brussels May 15-18, 1958. The Vienna congress will be under the direction of Prof. Dr. Felix Mandl and Prof. Dr. Leopold Schonbauer, of the surgical department, University of Vienna. The meeting will bring together the German, Austrian, Dutch, Swiss, and other sections. About 75 papers will be presented. Sessions will be held in Billroth-Haus, Vienna. Nine surgeons will participate in a symposium on "Surgery of Athletic Injuries." Scientific themes will include "Diseases of Connective Tissues," "Modern Therapy of Malignancies," "Errors in Diagnosis and Therapy," "Bone Tumors," and "Contrast Visualizations of Internal Organs, Their Value and Dangers." Entertainment will include a reception in City Hall, a visit to the opera, and tours. Inquiries about scientific matters should be addressed to Dr. Felix Mandl, Reichsratsstrasse 11, Vienna I.

The Brussels congress will bring together the Austrian, Belgian, English, Finnish, French, German, Greek, Italian, Dutch, Spanish, Swiss, and Turkish sections. The meeting will be under the auspices of the Belgian section and the direction of Prof. Dr. John Henri Oltramare, of the University of Geneva and director of the European Federation, and Drs. Leopold Lambert, André Sondervost, and G. F. Van Keerbergen, president, secretary, and vice-president, respectively, of the Belgian section. For information write the Secretariat, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10, Ill.

DEATHS IN OTHER COUNTRIES

Sir Charles Read.—The president of the Royal College of Obstetricians and Gynecologists, Sir Charles Read, was taken ill aboard his yacht recently and died soon after reaching a hospital in Dartmouth, England. Sir Charles was appointed president of the Royal College of Obstetricians and Gynecologists in 1955 and was reelected this year. He was an honorary fellow of the American Association of Obstetrics, Gynecology, and Abdominal Surgeons and the American Gynecological Society. Over a period of years he had instructed medical students at Charing Cross Hospital and Medical School and other institutions, and postgraduate students at Hammersmith and Chelsea Hospital for Women. Born in Dunedin, New Zealand, Sir Charles studied at the University of Otago, Dunedin, and the Otago Medical School, where he won honors in clinical medicine.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part I.* Various Centers, Sept. 3-4. Sec., Dr. John B. Hubbard, 133 South 36th St., Philadelphia 4.

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Washington, Oct. 28-Nov. 1. Various locations in the United States and Canada, July 18. Final date for filing application is Jan. 18. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology: *Oral.* Baltimore, Oct. 11-13. Final date for filing application was April 1. Sec., Dr. Beatrice Maher Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *Written.* Oct. 21. *Oral.* Los Angeles, Sept. 11-14. Final date for filing applications was Feb. 1. Exec. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology. Various locations in the United States and Canada. *Part I.* Jan. 2. *Part II.* Chicago, May 7-17. Final date for filing application is September 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Oral.* Chicago, Oct. 7-11. *Written.* January 1958. Final date for filing application was July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Part I.* April 3-4, Rochester, Minnesota, Denver, Colorado, Washington, D. C. Final date for filing application is Nov. 30. *Part II.* New York City, Jan. 29-31, 1958. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: Chicago, Oct. 7-11. Final date for filing application was in April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Oral and Written. Pathologic Anatomy and Clinical Pathology.* New Orleans, Sept. 26-28. Final date for filing application is August 15. Sec., Dr. Edward B. Smith, Indiana University Medical Center, Indianapolis 7.

American Board of Pediatrics: *Oral.* Chicago, Oct. 11-13. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written Examination.* San Francisco, Oct. 31-Nov. 2. Final date for filing case reports was July 1. Corresponding Sec., Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *In Public Health. Oral and Written.* Cleveland, Nov. 7-9. Sec., Dr. Thomas F. Whayne, 3438 Walnut St., Philadelphia.

American Board of Proctology: *Oral and Written. Parts I and II.* September. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New York, Dec. 16-17. San Francisco, March 17-18. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S. W., Rochester Minn.

American Board of Radiology: Washington, Sept. 23-28. Final date for filing application was June 1. Chicago, May 20-24. Final date for filing application is Jan. 1, 1958. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part II.* Buffalo, Sept. 23-24; New Haven, Oct. 21-23; Indianapolis, Nov. 18-19; Cincinnati, Dec. 16-17; New Orleans, Jan. 13-14; Durham, N. Car., Feb. 10-11; Baltimore, March 10-11; Chicago, May 12-13; Los Angeles, June 16-17 and Portland, Oregon, June 20-21. Sec., Dr. John B. Flick, 22' So. 15th St., Philadelphia 2.

American Board of Urology: *Written examination.* Various cities throughout the country. *Pathology and Oral Clinical.* February 1958. Location not decided. Exec. Secretary, Mrs. Ruby L. Griggs, 30 Westwood Road, Minneapolis 16.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, Sept. 6, and the closing date for registration was July 1, 1957. Sec., Dr. William H. Tuttle, 1151 Taylor Ave., Detroit 2.

ical Society; served as vice-president of the Blue Island Chamber of Commerce; on the staffs of Ingalls Memorial Hospital in Harvey and St. Francis Hospital, where he died Aug. 1, aged 66, of heart disease.

Quay, William Hendricks, Wilkes-Barre, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1894; an associate member of the American Medical Association; veteran of the Spanish-American War; medical examiner for the selective service boards during World Wars I and II; formerly practiced in Meadville, where he was on the staffs of the City and Spencer hospitals; served on the staff of the Titusville (Pa.) Hospital; died in Bloomsburg, July 7, aged 86.

Shaver, William Trantham, Albemarle, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1919; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; served as president of the Stanly County Medical Society and the Seventh District Medical Society; veteran of World War I; on the staff of the Stanly County Hospital; surgeon for the Southern Railway; died July 16, aged 63, of heart disease.

Averill, Zelpha Walker, Mansfield, Ohio; Laura Memorial Woman's Medical College, Cincinnati, 1897; served on the board of the Mansfield General Hospital; died July 20, aged 84.

Baker, Bryant Orland ⊕ Dallas, Texas; Baylor University College of Medicine, Dallas, 1938; member of the American Academy of General Practice; died July 24, aged 56, of acute myocardial infarction and coronary arteriosclerosis.

Banks, Eldridge James ⊕ Ellisville, Miss.; Memphis (Tenn.) Hospital Medical College, 1905; died in Jackson July 29, aged 85.

Barnett, Spurgeon Hemperley, Little Rock, Ark.; St. Louis College of Physicians and Surgeons, 1917; Kansas City (Mo.) College of Medicine and Surgery, 1920; died July 16, aged 71.

Barshay, Bernard, Castle Point, N. Y.; Tufts College Medical School, Boston, 1927; service member of the American Medical Association; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; chief of the laboratory service, Veterans Administration Hospital, where he died May 16, aged 54, of coronary occlusion.

Christie, Ralph Conklin, Long Beach, Calif.; University of Nebraska College of Medicine, Omaha, 1909; an associate member of the American Medical Association; veteran of World War I; formerly member of the city council and of the city water commission; died Aug. 2, aged 74, of cancer.

Farnham, Waldo Clay, St. Petersburg, Fla.; Northwestern University Medical School, Chicago, 1910; veteran of World War I; died in the Mound Park Hospital June 24, aged 75, of myocardial infarction and coronary thrombosis.

Farrage, James H., Santa Ana, Calif.; University of Louisville (Ky.) Medical Department, 1911; an associate member of the American Medical Association; on the staff of the Santa Ana Community Hospital; died in St. Joseph Hospital June 6, aged 78, of cerebral thrombosis.

Guy, Robin Jefferson, Paynesville, Mo.; St. Louis College of Physicians and Surgeons, 1910; died June 13, aged 69.

Hawks, Edwin Andrew Jr., Tulsa, Okla.; Washington University School of Medicine, St. Louis, 1895; died May 30, aged 83, of a heart attack.

Hersohn, William Wolfe ⊕ Atlantic City, N. J.; Jefferson Medical College of Philadelphia, 1933; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; veteran of World War II; associated with the Atlantic City Hospital and the Shore Memorial Hospital in Somers Point, where he died July 17, aged 56, of acute myocardial infarction.

Howell, Harriett, San Jose, Calif.; Hahnemann Hospital College of San Francisco, 1896; died June 25, aged 82.

Laroche, Armand ⊕ Rutland, Mass.; University of Montreal Faculty of Medicine, Montreal, Quebec, Canada, 1922; member of the American Trudeau Society; assistant superintendent, Rutland State Sanatorium; died in the Kerbs Memorial Hospital, St. Albans, Vt., July 6, aged 60, of emphysema and renal tuberculosis.

Lesem, Alexander Marx ⊕ San Diego, Calif.; College of Physicians and Surgeons, Los Angeles, 1914; served as city and county health officer; died July 16, aged 77, of a heart attack.

Loftus, Michael Emmet, Indianapolis; Louisville (Ky.) Medical College, 1904; died July 23, aged 77, of a heart attack.

McCartin, John Edward, Boston; Tufts College Medical School, Boston, 1908; on the staff of the Massachusetts General Hospital; died June 22, aged 78, of coronary occlusion.

McGuire, Roy Alvin ⊕ Fairfield, Iowa; State University of Iowa College of Medicine, Iowa City, 1908; member of the American Academy of General Practice; past-president of the Jefferson County Medical Society; formerly practiced in Brighton, where he was mayor and a member of the school board; member of the school board in Fairfield; died July 19, aged 76.

FOREIGN LETTERS

CANADA

Aseptic Meningitis with Rubelliform Rash.—In 1956, Toronto virologists described the occurrence of 96 cases of aseptic meningitis, in about half of which a virus was probably involved. In the *Canadian Medical Association Journal* (77:1, 1957) they report a further outbreak in Toronto and vicinity in 1956. There were 115 cases in children, and the most interesting clinical feature was the presence of a rubelliform rash in 50. Many other children were treated at home, and some adults were also affected, with an encephalitis occurring in most. The cell count in the spinal fluid was unusually high, with many neutrophils in the differential count, but the fluid was sterile. The condition seems to be new in Toronto, and some cases were probably due to a virus related to Echo virus type 9. Strains isolated by tissue culture were pathogenic for suckling mice and caused myositis. They were not neutralized by antiserums to viruses of Coxsackie types A9 or B1-5.

Parotitis with Herpangina.—Howlett and Somlo reported four cases of what they considered a new entity, parotitis and herpangina associated with the presence of Coxsackie virus, group A (*Canad. M. A. J.* 77:5, 1957). The patients had a parotitis, fever, and herpetiform lesions in the mouth and throat. In all four cases the presence of Coxsackie virus was demonstrated in throat washings, and in two cases in the stool as well, by the characteristic lesions produced in suckling mice that had developed paralysis and myositis. No evidence of mumps or herpes virus infection was found.

Fluoridation Ruled Illegal.—The Supreme Court has ruled that metropolitan Toronto cannot add fluorine compounds to the water it supplies to 13 municipalities. The argument began when one of the municipalities, Forest Hill, sued Toronto, which was proposing to fluoridate the water. The first local decision was that the senior authority was perfectly entitled to do so, but the Ontario Appeal Court reversed this decision, and when Toronto carried its case to the Supreme Court the latter endorsed the Ontario Appeal Court's decision by five to two. The majority decision says that the new Metropolitan Toronto bylaw is not aimed at making the supply of water more pure and wholesome but is designed "to cause the inhabitants of the Metropolitan area, whether or not they wished to do so, to ingest daily small quantities of fluoride in the expectation that this will render great numbers of them less susceptible to tooth decay." Hence the bylaw is considered to have exceeded the powers conferred by the Ontario legislature. This raises the question as to whether other Ontario municipalities that have already fluoridated their water are acting beyond their legal powers. The situation could be put right by fresh legislation at the next session of the Ontario Provincial Parliament.

Voluntary Hospital and Medical Insurance.—At the end of 1955, about 6,700,000 persons, or nearly 43% of the Canadian population, had some form of voluntary hospital insurance, and 5,800,000, or 37%, of the population had medical insurance contracts to assist in paying for physicians' services. The hospital insurance figures must be read in conjunction with the fact that in four provinces there are public hospital schemes run by province and/or municipality and covering most of the population, so that voluntary coverage there is confined either to persons not eligible to participate in the provincial scheme or to those wishing additional benefits such as private ward care. Thus, though the rate of growth of membership in voluntary schemes has flattened out in recent years, it still continues. The percentage increases in membership during 1955 were as follows: nonprofit hospital insurance 6%, private hospital insurance 8%, nonprofit medical insurance 16%, and private medical insurance 8%. Ontario is the leading province as regards percent of population covered, both in voluntary hospital insurance (71%) and in medical care insurance (51%).

The Smoker's Lung.—Hamilton and co-workers (*Canad. M. A. J.* 77:177, 1957) made histological sections of the bronchial mucosa from autopsy material. Classification was made as to nonsmokers, smokers, and those with bronchogenic carcinoma. (In the last group the lung opposite to that affected by the tumor was sectioned.) They observed the following five types of morphologic change in the lining epithelium of the bronchi: basal cell hyperplasia, stratification, squamous metaplasia, transitional metaplasia, and intermediate change. The most significant difference between the three groups was that basal cell hyperplasia was present in 80% of patients with carcinoma, 86% of smokers, and only 40% of nonsmokers. It is impossible to say whether this change is due to smoking or is even

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

precancerous, though it certainly suggests that something has caused an altered growth and maturation pattern in the epithelium.

Symposium on Fluothane.—The July issue of the *Canadian Anaesthetists' Society Journal* contains a symposium on the newly studied fluorinated hydrocarbon, Fluothane (2-bromo-2-chloro-1,1,1-trifluoroethane), a volatile anesthetic. This drug has been tried in several cities. Chang and co-workers used it as an anesthetic in 310 patients, in 120 with a closed and in 190 with a semiclosed technique. Induction was either by thiopental intravenously or by gas, oxygen, and Fluothane by mask. The chief advantages of the drug are that it is noninflammable and nonexplosive and does not cause respiratory irritation. It reduces bleeding and allows good control of respiration. Recovery is moderately rapid and postoperative vomiting rare. However, it does cause cardiovascular depression, often severe, and also respiratory depression, and it may cause cardiac arrhythmias. Relaxation is only moderate, and the drug is incompatible with epinephrine.

After using it on 1,112 patients in Quebec City, Hudon found that it gave a pleasant induction and led to no anxiety provided it was administered smoothly and without a sudden increase in concentration, which can cause cardiac depression and dangerous hypotension. The absence of bronchoconstriction, laryngospasm, and excessive bronchial secretion aids pulmonary ventilation. It decreases capillary oozing and seems to combat shock. MacKay of Toronto used it on 203 patients and found that it could be used by the open drop method for mass casualties. He strongly recommends avoidance of a closed method and finds the use of a continuous flow nonrebreathing circuit (nitrous oxide and oxygen) with a temperature compensated vaporizer, the Fluotec, most satisfactory. Other reports drew attention to the value of Fluothane in pediatric anesthesia and in neurosurgery.

Is Tonsillectomy Always Justified?—Le Riche and Stiver (*Canad. M. A. J.* 77:109, 1957) made a statistical study of the tonsillectomies performed on subscribers to a nonprofit medical care plan in Ontario over a six-month period. There were 4,281 cases, and the annual tonsillectomy rate per 1,000 participants in 12 counties was found to vary between 29.0 and 3.5 (average 19.8). Another study showed that the rate was no higher in subscribers than among those not covered by insurance and that more rural than urban patients lost their tonsils. Because of the great variation in rates by county, the authors examined the preoperative and postoperative histories of 1,000 patients, mostly children, to see whether they were any healthier after the operation. There was a marked reduction in physicians' calls for nasal and pharyngeal infections in the year after operation. On a basis of call for acute pulmonary infections, 54% of the patient appeared to have benefited. No benefit was foun in patients with allergic rhinitis. In 135 patient there was no preoperative history of pulmonary o pharyngeal disease, and it is concluded that th tonsils were removed because of their appearanc

DENMARK

Treatment of Alcoholism.—*Five articles in Ugeskri for læger* for June 6 and July 4, 1957, throw som light on what is being done to combat alcoholism Dr. I. Venge gives an account of the ambulatoriu and the sanatorium which have been in operatio since April, 1953. The ambulatorium is attached the Copenhagen City Hospital, and the sanatoriu is established at Jaegersborg. The two are under the same chief and are served by the same staff. Disulfiram is given to all patients, the only contraindication being some serious disease such as uncompensated or severe heart disease. Venge believes too much must not be hoped for from psychotherapy, especially when applied on any wholesale scale. The best form of psychotherapy is by means of a close association between the patient and a social worker acting as a custodian under the supervision of a psychiatrist. More than 33% of the author's patients show improvement, a higher rate than is observed in the treatment of other neurotic and psychopathic conditions. Dr. L. M. Sonne reports on the work of the psychiatric department of the Bispebjerg Hospital to which 610 alcoholics were admitted in 1955. While 28% of the male psychiatric patients admitted were the victims of alcoholism, this was so with barely 5% of the women. In 33% there was a history of attempted suicide.

Cancer of the Lung.—*The thoracic surgery department of the Oresund Hospital in Copenhagen issued a study by Dr. C. M. Smidt entitled "The Diagnosis of Lung Cancer." A comparison of the symptoms of the 172 patients found to be suffering from lung cancer with symptoms of 823 other patients not suffering from cancer has led to the conclusion that in its early stage lung cancer presents no specifically characteristic symptoms. Such roentgenographic changes as atelectasis in a patient of the lung cancer age may be suggestive but none of these changes can be said to be pathognomonic of lung cancer. Bronchography is a useful supplement to the diagnosis of lung cancer, but by itself it does not warrant either the confirmation or the invalidation of such a diagnosis. In Smidt's material there were 77 patients in whom the diagnosis of lung cancer could not be confirmed or ruled out by a combination of tests. They were therefore subjected to an exploratory thoracotomy. Thirty-two patients were found to have lung cancer.*

ISRAEL

Poliomyelitis.—A dramatic drop in the incidence of poliomyelitis was recorded in June, 1957, as compared with June, 1956—6 cases and no deaths as compared with 64 cases and 3 deaths; in May, 1957, there were 4 cases and no deaths compared with 26 cases and 3 deaths in May, 1956. While Ministry of Health sources are still cautious about attributing this decline to the national Salk vaccine program, there is an unmistakable feeling of quiet jubilation among its officials. A breakdown of the first six months of this year as compared to 1956 shows 10 cases in January as compared with 10 cases and one death in January, 1956; February, no cases as compared with 4 and one death; March, 3 cases as compared with 4 and one death; and April, no cases compared with 8 and one death. Of the children who contracted the disease this June, only one had been inoculated with Salk vaccine.

Hearing Tests on School Children.—E. Korine (*Harefua* 52:262, 1957) reported a series of 17,000 audiometric hearing tests in school children. Hearing loss in children is not always noticed by the parent or the teacher, but the child with defective hearing is severly handicapped in his studies or may be wrongly accused of laziness. The results of these tests showed that 7% of the school children suffered from loss of hearing; 5% needed medical treatment for such conditions as otitis media, adenoiditis, and tonsillitis. One in a 1,000 needed rehabilitation through lip reading and hearing aids. These findings are almost identical with those of the United States and England. It may be assumed that, of Israel's 300,000 school children, about 15,000 need otological treatment and supervision for loss of hearing.

Idiosyncrasy to Meprobamate.—E. Davis (*Harefuah* 53:37, 1957) reported two cases of hypersensitivity occurring during meprobamate medication. Both cases are outstanding, because after the patients had taken only one tablet of 400 mg. of meprobamate, an allergic reaction occurred in the form of generalized urticaria in the first patient four hours and in the second five hours after the tablet was taken. After four days, the reaction subsided without specific therapy. One of the patients had a history of allergy to penicillin, and the second had had allergic reactions to various medicaments. These two reactions appeared among 20 patients treated with the drug.

Cortisone in the Treatment of Sterility.—According to Polishuk and Hochstaedt (*Harefuah* 53:57, 1957), the increased production of androgenic hormones by the adrenal cortex, as seen in the adrenogential syndrome and related conditions, impairs the menstrual mechanism by a direct effect on the endometrium and by depressing the pituitary gonadotropic hormones, thus causing amenorrhea, nonovulatory cycles, or corpus luteum deficiencies. In patients complaining of sterility, cortisone has been given to inhibit stimulation of the adrenal cortex, decrease androgen production, and permit a normal relationship between the pituitary gonadotropins and the ovaries. Eleven patients were selected for treatment with cortisone according to the following criteria: (1) sterility of over two years' duration, (2) presence of ovarian dysfunction (amenorrhea, nonovulatory cycles, or corpus luteum defects), (3) clinical signs of masculinization, and (4) increased excretion of 17-ketosteroids. In all patients any other cause of sterility was first ruled out. Cortisone was given for six to eight weeks. Initial doses were 75 mg. daily for two weeks, with the dose gradually decreased to 25 mg. daily. Seven of these patients became pregnant. Of these, four had normal deliveries, two have not yet been delivered, and one had a tubal pregnancy. The effects of cortisone administration on ovarian function lasted from four to six months. No abnormalities were noted in the infants born to the mothers.

JAPAN

Orphans.—The Japanese children's bureaus are caring for over 60,000 orphans, many of whom owe their lives in part to some members of the United States armed forces. The present reduced budget provides food at a bare subsistence level, and the women who care for the children day and night are grossly underpaid. Bales of discarded clothes shipped from the United States help out the budget. The diet of these children is notably deficient in calcium and vitamins. One group of veterans who saw service in Japan has formed a club, the purpose of which is to extend moral and financial aid to about 600 orphans on the Isle of Sado. This is the first real helping hand stretched across the sea for the helpless orphans.

Homicidal Instructors.—On two occasions students in Tokyo were beaten to death by one of their instructors. Corporal punishment by a teacher is strictly forbidden, but the school authority lacks sufficient psychiatrists to weed out the misfits from the teaching profession.

PERU

Giant Hypertrophic Gastritis.—At a meeting of the Faculty of Medicine of Lima, Dr. Daniel Becerra de la Flor, auxiliary professor of surgery, reported a case of giant hypertrophic gastritis. Less than 12 cases of this disease have been reported. A 74-year-old woman was admitted to the hospital in August, 1955. She had been in good health until five months prior to admission when she began to suffer fr dull epigastric pain radiating to the umbilicus and the right hypochondrium. In the two months before she was admitted, the pain became continuous and more severe, and anorexia, nausea, vomiting, loss of weight, insomnia, and increasing weakness developed. The vomiting occurred after food intake, and at times the vomitus contained food particles ingested four or five days earlier. When vomiting occurred without the ingestion of food, the vomitus was acholic and consisted of glairy mucus. No hematemesis nor melena were noted. A tumor could be felt in the epigastrium and right hypochondrium, but early in the course of the disease this would disappear when massaged. This would be followed by a relief of the symptoms, but later, massage gave no relief.

Physical examination revealed an emaciated woman with marked edema of the legs and tenderness over a firm, irregular, epigastric tumor. The blood protein level was 5 Gm. per 100 cc., and there was a mild hyponatremia. Free acidity was absent in the gastric secretion and eight units were elicited by histamine stimulation. Cytological examination of the stomach contents failed to reveal neoplastic cells. A gastrointestinal series revealed a hypotonic and hypoperistaltic stomach with a rough defect in the antral region and inability of the barium to pass into the duodenum. The radiologist made a tentative diagnosis of gastric neoplasm. At operation, six days after admission, almost half of the stomach was found to be invaginated into the first portion of the duodenum, which was enormously lengthened. A Polya's partial gastrectomy was performed. The resected segment included a polypoid, sessile, irregular, brain-shaped mass that was elevated 3.5 cm. above the normal surrounding tissue. Histological examination revealed a giant hypertrophy of all the normal constituents of the gastric mucosa. The patient made an uneventful recovery.

SWEDEN

Lobectomy for Pulmonary Tuberculosis.—In *Nordisk medicin* for June 20, Dr. V. O. Björk gave an account of the 301 lobectomies he performed for pulmonary tuberculosis. He found advanced age no contraindication, and among his patients were five operated on after they were 60. While four of them tolerated the operation well, the fifth, aged 64, died two days after the operation with signs of coronary insufficiency. The indications for operation were cavitation in 85%, bronchial stenosis in 9%, bronchiectasis in 2%, tuberculous pneumonia in 2%, and tuberculous empyema with a bronchial fistula in 2%. A cure could be claimed in 85% on the strength of negative guinea pig and sputum tests. The 15% for whom a cure was not claimed consisted of patients in whom tubercle bacilli were still demonstrable. The resected portion of the lung having already been largely destroyed by tuberculosis, the loss of this portion by operation did not appreciably reduce the gas exchange or ventilation of the lung on the side operated on. There was, however, a significant diminution of the maximum ventilation capacity. In 283 patients, the resection was combined with a plastic operation, and there were only 18 patients in whom the lobectomy was independent of any simultaneous operation designed to reduce the capacity of the chest. Björk noted, however, that several of his patients with pulmonary tuberculosis had cavitation with the disease confined to one lobe. For such patients primary lobectomy can be performed without any supplementary plastic operation. These comparatively new cases are in marked contrast to older series in which tuberculosis was usually bilateral and most of the patients had previously undergone pneumothorax on one or both sides.

Surgical Treatment of Peptic Ulcer.—Dr. S. Richter (*Nordisk medicin*, June 20, 1957) has reviewed his experiences of the last 20 years during which he treated 2,765 patients with peptic ulcer. There was no evidence that patients subjected to gastric resection are peculiarly liable to contract pulmonary tuberculosis. Dr. S. Grettve reported on a series of 283 gastric resections. While he had no postoperative deaths among his 246 patients with chronic recurrent ulcer, he had two such deaths among the 27 patients with perforation of the ulcer. His follow-up examination showed that 70% of his patients were completely free of gastric symptoms, though several of them had some slight difficulty with their food suggestive of the dumping syndrome. This did not, however, impair their capacity for work. Grettve concluded that the Billroth 2 operation insures a low mortality and small risk of relapse.

Traffic Accidents.—Traffic accidents now cost Sweden 269 million krona yearly. Dr. Ivar Palmer (*Nordisk medicin*, Aug. 8, 1957) has reviewed the findings of the Northern Surgical Congress held in Stockholm last summer. It was pointed out but not statistically proved that the noise of motor traffic must to some extent be held responsible for traffic accidents by virtue of the irritation it causes. This factor has not been measured, and, if it is to be done, money must be spent on research. The noisy motor bike causes three times as many road accidents as the motor car, although cars outnumber motor bikes. Research is also needed into the influence of poisons such as gas fumes, carbon monoxide from the engine or a cigaret, and hypnotics, but not including alcohol, on road accidents. At present these potential offenders are neglected in favor of alcohol, the importance of which has been rated so highly that a blood concentration of only 0.05% is enough to convict a driver of careless driving. In practice this means that the physician likely to be called on to drive a car at any time must not even take a bottle of beer, which is enough to raise the concentration of alcohol to the above level. The part played by alcohol has hitherto caught the attention of the traffic authorities with almost monomaniacal interest. Drunkenness in traffic must be combated as effectively as possible, but one is tempted to ask if the campaign against it has not been overzealous.

Is Neglect of Antitetanic Serum Defensible?—A disciplinary case brought to the attention of the Swedish Doctors' Liability Committee has again raised doubts over the decision for the prophylactic administration of antitetanic serum as soon as a serious wound has been inflicted. The patient was a 7-year-old girl who fell on a splinter of glass which opened a 2-cm. wound on the flexor aspect of her right hand. The girl was promptly taken to a polyclinic, where her wound was treated with hydrogen peroxide and then sutured. She was told to return a week later, but when she did so the wound was found to be purulent. Sutures were removed and the wound opened so as to allow the escape of pus. A dressing was applied, and the faulty position of the hand was corrected by a splint. Antitetanic serum and toxoid were given, because stiffness of the neck, lower jaw, and right arm had been detected the day before. The girl died a few days later of tetanus. Her father appealed to the liability committee, whose experts gave a cautiously worded judgment which is published in *Svenska läkartidningen*, Aug. 16. To the complaint that serum had not been given sooner, it was answered that, as far as could be ascertained, there had been no error or neglect in the treatment given; but the comments of one of the experts on the case imply that washing with hydrogen peroxide does not by itself satisfy the rulings of the Swedish Surgeons' Association on the prevention of tetanus.

UNITED KINGDOM

Maternal Mortality.—An editorial in the *British Medical Journal* of Aug. 3 draws attention to certain defects which persist in spite of the march of progress. In 1928, 2,920 women died as a result of pregnancy or from causes directly associated with it. In three years, 1952 to 1954, there were 1,987 deaths under this same heading. The four leading causes of deaths were toxemia (22%), hemorrhage (17%), abortion (14%), and pulmonary embolus (13%). Sepsis accounted for only 3.8% of these deaths, and this remarkable decrease is the most outstanding factor in the reduction of maternal mortality. Twenty-five years ago sepsis was responsible for more than 33% of maternal deaths. Among the 316 "associated" deaths, heart disease was the most common cause, accounting for 121. There were 183 deaths after cesarean section and 49 due to complications of anesthesia.

Since eclampsia can be prevented by rigid prenatal supervision, it is discouraging to note that 110 mothers died from this disorder. The most glaring deficiency was in the quality of prenatal care. A number of these deaths were clearly due to lack of cooperation between physician, midwife, clinic, or hospital. Shortage of antenatal beds has been blamed for late admission of patients with severe preeclampsia, but this is not reasonable justification for a hospital sending "home to bed" a patient with albuminuria, edema, and blood pressure of 168/110 mm. Hg. Another patient whose blood pressure was 220/130 mm. Hg was allowed to return home. Again, when so much time is spent in teaching the importance of an early rise of blood pressure, it is hard to understand why a mother was not admitted to hospital when her systolic blood pressure was over 200 mm. Hg.

It is believed that half of the deaths from hemorrhage in antepartum cases and 90% in the postpartum group could have been prevented. Deaths from postpartum hemorrhage with retained placenta presented a higher proportion of avoidable factors than any other group. In many instances the "flying squad" was called too late, or the patient was removed to hospital without resuscitation or with the placenta undelivered. These squads should not be staffed by junior medical officers. The family physician or midwife needs expert help when calling for it, and an experienced obstetrician and anesthetist should always be members of the team. It was not always in the home that attendants did not appreciate the dangers of slow, continuous hemorrhage. Perhaps when ergonovine maleate is given routinely with the delivery of the baby, these tragedies, almost wholly preventable, will no longer appear in maternity reports. There were very few avoidable factors in deaths from pulmonary embolus, but, in cases of abortion, it was a different story. Many do not realize that it is most often the married woman with a family who succumbs to the complication of procured abortion; there were 85 such cases.

The report issued by the Ministry of Health recommends that there should be (1) better antenatal care, especially in early detection and early treatment of toxemia; (2) more prompt and more effective treatment of hemorrhage, especially through the use of "flying squads" for the emergencies of domiciliary midwifery; and (3) better selection of patients for specialist care at the hospital, especially women in the older age groups and higher parities. Time and again the report underlines the lack of teamwork between those responsible for the care of the expectant mother.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Obliterative Brachiocephalic Arteritis: Pulseless Disease of Takayasu. T. B. Gibbons and R. L. King. Circulation 15:845-849 (June) 1957 [New York].

The authors report a 42-year-old woman with obliterative brachiocephalic arteritis, a rare vascular disease. Except for a fractured clavicle in childhood, there was no history of trauma and no evidence of aortic aneurysm or dissection or syphilitic infection. The patient was admitted to the hospital for study of low blood pressure and claudication in the left leg, right arm, and jaw. She also had a feeling of weakness of the eyes "as if they would cross" followed by a sensation of slow gyrations in the head and partial loss of balance. Each spell lasted from 4 to 10 minutes and was followed by nausea. Ophthalmoscopic examination revealed slight glaucomatous cupping but no evidence of cataracts, corneal opacities, or vascular looping in the region of the optic disk. The axillary arteries were not pulsatile to palpation; both radial arteries were weakly palpable at times, but ulnar pulses were absent. The left popliteal and dorsalis pedis arteries and both posterior tibial vessels were nonpulsatile. Blood pressure was determined with great difficulty in the arms. With the patient supine the systolic pressure in both arms was estimated to be around 70 mm. Hg. With the patient sitting up or standing, an arterial pressure could not be detected in either arm. Blood pressure in the legs was 145/80 mm. Hg on the right and 90/80 mm. Hg on the left. The patient was given 10 mg. of prednisone orally every 6 hours. Bishydroxycoumarin (Dicumarol) was employed to maintain the prothrombin concentration between 10 and 20% of the control. The patient was discharged after 10 days to continue the same therapy at home. Six weeks later the patient reported a gradual subjective improvement, having been free of jaw and arm claudication since leaving the hospital. There was also an increased capacity for walking before the appearance of claudication in the left leg. She continued to have occasional transient blurring of vision. An angiocardiogram was performed, and the first portion of the innominate artery, the entire left subclavian artery, and the proximal segment of the left common carotid artery were not visualized. The right subclavian artery could be faintly traced at its junction with the right common carotid artery, but not distal to this point. The axillary arteries and the distal portions of the carotid arteries, including their bifurcations, were clearly seen and appeared normal.

The case of this patient did vary from the typical case of brachiocephalic arteritis in 3 respects: there was no objective evidence of organic damage to the eyes beyond glaucoma, the patient did not have carotid sinus syncopal attacks, and she apparently did have involvement of the left iliac artery, but all these variations have been described in patients with Takayasu's disease. At present the patient is being maintained on 15 mg. of prednisone per day and sufficient Dicumarol to provide a desired degree of hypoprothrombinemia. The therapeutic results obtained with these 2 drugs thus have been encouraging. Although the case of this patient is only the third of this disease to be reported in this country, 5 probable cases have been described under other diagnoses. In contrast, nearly 100 cases have been recognized in Japan and Europe.

Retrosternal Novocaine Anesthesia Therapy of Coronary Insufficiency. F. E. Ostapiuk. Terapevticheskiy Arkhiv 29:58-70 (No. 4) (April) 1957 (In Russian) [Moscow].

The method consists of passing a needle 15 to 18 cm. long into the jugular fossa and passing it downward behind the sternum until aortic pulsations are felt. From 60 to 80 cc. of 0.5% solution of novocaine is then injected into the anterior mediastinum. Three hundred twenty such injections were given to 59 patients, to 9 of these at the time of myocardial infarction and to 264 between anginal attacks. The injections were given to 7 patients once weekly and to the rest at intervals of 1, 2, 3, and 4 days. The number of injections given to an individual patient varied from 1 to 10. The result of the treatment in 32 patients was a complete cessation of the anginal attacks. In a group of 9 patients attacks became less frequent, and in a group of 5 patients the treatment proved ineffective. The authors conclude that novocaine anes-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1948 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

thesia therapy is effective in coronary insufficiency. The anesthesia of the para-aortic and cardiac plexuses produces anesthesia of the pain conducting fibers and improves the coronary circulation by the dilating effect upon the coronary arteries. Extrasystoles, paroxysmal tachycardia, atrioventricular block, and block of the bundle of His do not constitute a contraindication to the above treatment. Blood pressure higher than 200/110 mm. Hg or low blood pressure (lower than 90/50 mm. Hg) constitutes a contraindication.

Prognostic Factors in Myocardial Infarction. G. E. Honey and S. C. Truelove. Lancet 1:1155-1161 (June 8) 1957 [London].

The records of all patients admitted with myocardial infarction to the Radcliffe Infirmary from 1940 to 1954 inclusive were analyzed together with those of a small number of patients in whom the disease developed while in hospital for other disorders. This first of 2 reports on 543 attacks of myocardial infarction is concerned with the prognosis in the acute attack (the 2 months after admission). One-third of the 195 deaths that occurred during these 2 months ensued on the first day. Thereafter the rate of dying fell off progressively. The presence of shock or hypotension or both when the patient arrived at hospital was associated with an increased risk of death within 48 hours of admission. Among patients who survived the first 48 hours, a different set of factors was associated with an increased risk of death during the rest of the acute attack. These were a history of cardiac asthma, evidence of cardiac failure (either left or right ventricular), cardiac arrhythmia (including multiple extrasystoles), gross cardiac enlargement, and diabetes mellitus. Factors which have been supposed to be associated with bad prognosis had no such association in the present series. These factors were a previous attack of myocardial infarction, previous angina of effort, previous breathlessness on exertion, and previous hypertension. Prognosis was likewise unaffected whether the onset was with the patient at rest or during exertion. Anticoagulant therapy was first used in this series of patients in 1948 and was in extensive use by 1952. The over-all effect of anticoagulant therapy on the death rate has not been very great, and the improvement can be accounted for by the almost complete abolition of deaths from pulmonary embolism.

Prognostic Factors in Myocardial Infarction. G. E. Honey and S. C. Truelove. Lancet 1:1209-1212 (June 15) 1957 [London].

This second report on prognostic factors in myocardial infarction reviews the long-term prognosis of the 348 survivors of the acute attack, which is defined as lasting 2 months from admission. About 1 in 7 of the survivors died during the remaining 10 months of the first year, and this rate was constant throughout the whole period covered by the study. In the second year a further 10% died. Thereafter, about 5% died each year. Bad prognostic factors, which can be recognized early in the acute attack, were evidence of cardiac failure (either left ventricular or congestive and not necessarily severe); cardiac arrhythmia including multiple extrasystoles; gross cardiac enlargement; and (though less important than the foregoing) a previous attack of myocardial infarction. Patients who displayed one or more of these features constituted a bad-risk group. They had 4 times the chance of dying in the remainder of the first year as did the patients with none of them. Over the course of 5 years, their chance of dying was double that of the *good-risk group. Age was of negligible consequence* in the long-term prognosis compared with whether the patient fell into the good-risk or the bad-risk group.

Among the good-risk group, the main cause of death within 5 years of the acute attack was recurrent infarction. The incidence of this was high among the patients under 60 and was the sole cause for their expectation of life being much worse than that of a sample of the same age and sex of the general population. By contrast, the patients of the good-risk group over 60 years had a low rate of recurrent infarction. Their expectation of life was the same as that of other people of their age and sex. Among the bad-risk group, recurrent infarction was common in both main age groups. In addition, cardiac failure not associated with another infarction was a potent cause of death.

Primary Cardiac Tumor (Sarcoma): Case with Unusual Clinical Course. V. Faber, E. Søndergaard and A. Bach. Ugesk. læger 119:696-698 (May 30) 1957 (In Danish) [Copenhagen].

Tumors of the heart are rarely included in diagnostic considerations, and, according to Engle and Glenn, the diagnosis of tumor of the heart has been made before death in only 14 cases. In the case of a primary sarcoma in the right atrium in a man aged 24 the multiple diffuse infiltrations in both lungs seen on roentgen examination could be interpreted as metastases, but neither heart auscultation nor electrocardiogram suggested primary localization in the heart. The clinical course was dominated by increasing hemorrhagic expectoration and anemia. There was no dyspnea or cyanosis. Autopsy disclosed the site of the primary tumor, which on microscopic examination was found to be a sarcoma. The necrotic hemorrhagic metastases in the liver were of the same character as the tumor tissue in the heart, and the metastases to the lungs showed mainly the same structure as those in the liver, but with more abundant cytoplasm.

SURGERY

The Beck Operation for Coronary Artery Disease. C. S. Beck and B. L. Brofman. Minnesota Med. 40:462-466 (July) 1957 [St. Paul].

Two things happen when a coronary artery is narrowed or occluded, namely, the production of electrical currents and the death of muscle. Electrical currents are produced in response to an increased oxygen differential, due to contact of poorly oxygenated muscle with well-oxygenated muscle, and the death of muscle occurs as a result of an inadequate blood supply. An ischemic area of muscle is capable of "triggering" a response in that it is acutely sensitive to slight increases or decreases in the blood supply, which reduce and increase its destructive power respectively. The heart is exceedingly vulnerable to small alterations in blood supply because of the precise segmental arrangement of the cardiac vascular network, where each coronary artery and each branch of a major coronary artery supplies a discrete segment of muscle. Some persons (9%) have variable connections between coronary arteries or their branches and are, thus, to a greater extent less vulnerable to coronary occlusion because of the existence of this collateral network. The Beck operation is a simple procedure consisting of 4 steps: passage of a ligature around and constriction of the coronary sinus down to a lumen of 3 mm.; abrasion of the lining of the parietal pericardium and epicardial surface of the heart; application of 0.3 Gm. of coarsely ground asbestos to the surface of the heart; and bringing of the mediastinal fat into contact with the heart to act as a graft. This procedure accomplishes several favorable ends: greater extraction of oxygen from the venous blood, a reduced oxygen differential, and the production of intercoronary channels. The only untoward result of this procedure is an increased capillary pressure leading to a reduced total coronary inflow. Contraindications for operation include signs of congestive heart failure (dyspnea at rest, rales, and peripheral edema), cardiac enlargement, and progressive symptomatology. Of 100 patients with a follow-up of 6 months to 5 years, 88% were improved and 90% were better able to work. In this series there were 100 consecutive operations with zero mortality.

Medical Aspects of the Surgical Treatment of Coronary Heart Disease. B. L. Brofman. Minnesota Med. 40:467-470 (July) 1957 [St. Paul].

Surgical intervention is indicated in patients who present clinical evidence that coronary artery disease has compromised the arterial blood supply. Contraindications are acute myocardial infarction or even a suspicion of an impending infarction, cardiac enlargement and evidence of congestive heart failure, and severe hypertension or any other associated disease that per se significantly limits life expectancy. Many of the patients in this series (75%) had suffered at least one clinically proved myocardial infarction, 2 or more infarctions having occurred in 20% and angina pectoris ranging in severity from mild to complete status anginosus in 95%. Patients with symptoms of longer duration (exceeding 3 years) tolerated the operation much better than those with symptoms of shorter duration. Operation is temporarily contraindicated in patients exhibiting anxiety and apprehension because of the specific deleterious effects (greater operative risk presumably in association with a lowered fibrillatory threshold) peculiar to patients so affected. The total mortality in a group of 225 patients was only 5% (11). A more recent series of 100 consecutive operations (30% salvage cases) resulted in only one fatality. Generally, the immediate postoperative course is uneventful, long-term follow-up revealing that 15 of the first 100 patients having severe "attacks" required hospitalization (3 instances of transmural myocardial infarction and 12 patients with one or more bouts of severe precordial pain), from which all recovered with no worsening of the symptoms and with the majority returning to work in 1 to 4 weeks. Complication such as severe narcotics addiction, psychoses, and cerebrovascular accident were disclosed in some of the few patients (10%) in whom long-term follow-up revealed no improvement. It is of interest that 3 patients having evidence of congestive heart failure prior to operation were better compensated postoperatively. Several patients obtained remission of, in addition to the common symptoms of coronary heart disease, some unusual manifestations, namely, premature ventricular beats (5%), reduction or absence of arterial pulses particularly in the left arm, sensory changes in the hands, and the shoulder-hand syndrome. A period of symptomatic improvement was abruptly terminated by overwhelming occlusion and death in half the patients who died 6 months to 5 years after operation. This result is not to be precluded by surgery, as the technique is symptomatic rather than prophylactic in nature.

Temporary Extracorporeal Circulation in the Surgical Treatment of Cardiac and Aortic Disease: Report of 98 Cases. D. A. Cooley, B. A. Belmonta, M. E. DeBakey and J. R. Latson. Ann. Surg. 145: 899-914 (June) 1957 [Philadelphia].

Temporary extracorporeal circulation has been developed for clinical application in surgical treatment of cardiovascular diseases. This report is concerned with the use of temporary extracorporeal circulation in 98 cases of cardiovascular disease. Temporary controlled extracorporeal circulation of 2 types was used, one being total cardiopulmonary bypass and the other simple unilateral bypass shunting blood from venous to venous or arterial to arterial regions. The method employed in the individual case depended upon the location and nature of the lesion. Total cardiopulmonary bypass was used in 88 and unilateral bypass in 10 patients. The oxygenator system was a bubble diffusion type, which produced consistently good oxygenation without serious hematological changes. Ventricular septal defects were repaired in 45 patients. Decrease in pulmonary pressure occurred at operation in all patients, and clinical improvement resulted in the 38 survivors.

Repair of atrial septal defects was usually well tolerated under cardiopulmonary bypass and is considered to be the method of choice for these defects. Among 12 patients operated upon 10 recovered and are apparently cured. Complete correction of tetralogy of Fallot was attempted in 7 patients, with 4 survivors, and in 4 patients with isolated pulmonary stenosis there were no deaths. Unilateral bypass was used successfully in 1 patient with combined infundibular and pulmonary valvular stenosis. For aneurysms of the descending thoracic aorta bypass around the lesion proved effective in preventing ischemic damage to the spinal cord during temporary aortic occlusion. In an addendum the authors state that since the completion of this report they have used total cardiopulmonary bypass in 52 patients and unilateral aortic bypass in 12. A stainless steel oxygenator has recently been used which is superior in many respects to the disposable plastic oxygenator.

Diagnosis and Treatment of Intracavitary Myxomas of the Heart. H. T. Bahnson, F. C. Spencer and E. C. Andrus. Ann. Surg. 145:915-926 (June) 1957 [Philadelphia].

The intracavitary myxoma is now accessible by surgery within the open heart. The authors present their experiences with 3 patients in whom they observed an intracavitary myxoma at operation. The first patient, a 53-year-old woman, had dyspnea and evidence of cardiac inflow stasis of 6½ years' duration. She had become refractory to remedies for cardiac failure. A short, soft systolic and a low-pitched rumbling diastolic murmur were heard adjacent to the sternum on the left. A diagnosis of intracavitary tumor of the right atrium was made after cardiac catheterization and confirmed by angiocardiography. The tumor was incompletely removed. Residual tumor, gastric dilatation, and electrolyte disturbances all probably contributed to death on the 24th postoperative day. The second patient, a 44-year-old woman with a 4½-year history of refractory right heart failure and intractable ascites, had an inconstant murmur suggesting mitral stenosis. Exploratory operation for the suspected stenosis revealed a tumor which was dislodged during manipulation and caused death from blockage of the left ventricle and thoracic aorta. The tumor arose from the atrial septum.

The third patient, a 57-year-old woman, was known to have had a cardiac murmur for 30 years and symptoms of fatigue, weakness, dyspnea, orthopnea, and hemoptysis for 20 years. Her condition had become refractory to treatment. A myxoma was unexpectedly encountered during exploration for mitral stenosis and later successfully removed during a cardiopulmonary bypass. To these cases treated surgically are added 6 additional cases undiagnosed before death and obtained from autopsy files. These cases are examples of the manners in which a myxoma may cause disability, namely, by cavitary obliteration, occlusion of the valve orifice, or arterial embolism. The tumor can be readily removed provided one is able to work within the open heart. For removal of a right atrial tumor, caval occlusion with the patient under hypothermia is suggested as the preferred method. The use of a pump oxygenator is advocated for a tumor of the left atrium. When a tumor is encountered during exploration for mitral stenosis, removal should be delayed until preparations for open cardiac surgery can be made.

NEUROLOGY & PSYCHIATRY

Congenital Absence of the Corpus Callosum: Report of a Case and Review of the Literature. U. T. Slager, A. B. Kelly and J. A. Wagner. New England J. Med. 256:1171-1175 (June 20) 1957 [Boston].

Of the 170 cases of congenital absence of the corpus callosum that have been reported, only 23, all diagnosed at autopsy, were asymptomatic. Some authors believe in the existence of a definite syndrome of absence of the corpus callosum. Others, although they do not recognize a syndrome, maintain that its absence or destruction results in neurological and psychiatric abnormalities. A third group proposes that no detectable deficiency results from absence or destruction of the corpus callosum. In support of this thesis, the 24th asymptomatic case of congenital absence of the corpus callosum, and the 16th case of complete absence in an asymptomatic adult, is presented. The patient was a 76-year-old man, who died 3 days after admission to hospital. Autopsy disclosed a recurrence of adenocarcinoma at the gastrojejunal anastomotic site, with metastases to the regional lymph nodes, colon, peritoneum, liver, pancreas, and common bile duct, producing compression of the common bile duct, with resulting hydrops of the gallbladder ending in rupture and bile peritonitis. Bronchopneumonia and an old posterior myocardial infarct were also found. Microscopic sections of the cerebral cortex, basal ganglions, pons, medulla, and cerebellum stained with hematoxylin and eosin revealed a normal cytoarchitecture, except for the complete absence of the corpus callosum. Moderate atherosclerotic changes were present. The function of the corpus callosum is apparently such that an adult can exist without this structure, living a normal life with normal intelligence and motor performance. The abnormalities such as idiocy, mental retardation, epilepsy, apraxia, and inability to concentrate, which are frequently reported, especially in children, are most probably due to anomalies usually associated with congenital absence of the corpus callosum.

GYNECOLOGY & OBSTETRICS

Feminizing Mesenchymomas (Granulosa-Cell and Theca-Cell Tumors) with Associated Endometrial Carcinoma: Review of the Literature and a Study of the Material of the Ovarian Tumor Registry. J. W. Greene Jr. Am. J. Obst. & Gynec. 74:31-41 (July) 1957 [St. Louis].

The author reports a 33-year-old woman who was admitted to the hospital of the University of Pennsylvania with the complaint of vomiting and gaseous distention of 11 days' duration. Menorrhagia had occurred during the last year, but no metrorrhagia. Abundant curettings grossly resembling carcinoma were obtained by dilatation and curettage. At laparotomy, the peritoneum, omentum, and intestine were found to be studded with tumor nodules. The ovaries were replaced by large masses of fungating friable tissue. Biopsies were taken from the ovaries and the omentum. The curettings showed endometrial glands composed of stratified cells with loss of cell polarity. In many areas, all semblance of basement membrane was lost and there was free invasion of the surrounding stroma by epithelial cells with numerous mitotic figures. The biopsies of the omentum and ovary showed cells of a microfolliculoid appearance with occasional rosette-like groupings about Call-Exner bodies, typical of granulosa-cell carcinoma. A diagnosis was made of a granulosa-cell carcinoma of the ovary with metastases to peritoneum, omentum and intestine, and of associated endometrial carcinoma.

The simultaneous occurrence of a feminizing mesenchymoma and carcinoma of the endometrium suggests the possible carcinogenic property of estrogens. This association has not been reported on previously in a woman aged less than 40 years in the English literature. One case was reported in the South American literature by Giordini in a 34-year-old woman with bilateral thecomas and carcinoma of the endometrium. A review of the slides and clinical histories of feminizing mesenchymomas contained in the ovarian tumor registry of the American gynecological society in which the endometrium was available for study revealed only 1 case of a feminizing mesenchymoma associated with carcinoma of the endometrium in a woman in the reproductive age. The author's case brings the total number of instances of these combined tumors to 132, of which 3 were in women aged less than 40 years.

The Role of Exfoliative Cytology in the Diagnosis of Carcinoma of the Cervix Uteri. E. H. Dale, O. A. Brines, G. S. Wilson and H. M. Nelson. Am. J. Obst. & Gynec. 74:25-30 (July) 1957 [St. Louis].

Of 15,832 presumably asymptomatic women from whom routine Papanicolaou smears were obtained in the course of 4½ years at a cancer detection center, a histopathological diagnosis of cancer of the uterine cervix was made in 151 (0.95%). Biopsies were performed in 140 women with positive smears; 123 (87.8%) of these confirmed the positive smear diagnosis. Fifty-one biopsies were performed in 77 women with suggestive smears, 27 (52.9%) of which were positive. Of the 151 women with cancer of the uterine cervix, 147 had squamous cell carcinoma; the tumor was invasive in 95 and apparently preinvasive in 39. The status of the remaining 13 patients was uncertain. Nearly 25% of the invasive and about 75% of the preinvasive carcinomas of the cervix were not recognized on vaginal inspection; consequently, history and physical examination only are not reliable methods for the diagnosis of cervical cancer.

Of the 151 women with histologically proved cancer of the uterine cervix, 52 (34.4%) were less than 40 years old. The cancer was definitely invasive in 24 of the 52 women. Thus in about 50% of the patients aged less than 40 years, the cancer had already progressed beyond the intraepithelial stage. This disease, therefore, has a higher incidence among the younger age group than has been generally thought. Routine Papanicolaou smears have been a most effective diagnostic aid in cancer detection and are credited with primary detection of 42.8% of all cancers of the cervix at Yates Memorial Clinic, staffed by the Wayne State University College of Medicine, and operated as a cancer detection center.

Facts Pertinent to the Etiology of Eclamptogenic Toxemia: A Summation of Previous Observations (1930-1955). R. A. Bartholomew, E. D. Colvin, W. H. Grimes Jr. and others. Am. J. Obst. & Gynec. 74:64-84 (July) 1957 [St. Louis].

An extensive review of the literature on the causation of eclamptogenic toxemia revealed certain significant anatomic, physiological, and pathological data on which a theory of the genesis of this disease has been based. There is a specific placental pathology in the form of acute and subacute placental infarction, best observed in formalin-fixed placentas, which is pathognomonic for preeclampsia, eclampsia, and abruptio placentae. This fact, first discovered by Young, is pertinent to the causation of the disease. Areas of placental necrosis in contact with maternal intervillous circulation present possibilities of dissemination of products of placental autolysis, which may be highly toxic to the mother. Placental infarction of the subacute or acute types is logically the cause and not the effect of toxemia of pregnancy. The paths and interrelationship of the fetal and maternal components of the placental circulation dictate this conclusion.

The anatomic basis of placental infarction is found in the presence of smooth-muscle sphincters in the placental veins, first discovered by Spanner. The trigger which excites spasm of few or many of the venous sphincters is logically oxytocin, which through changes in hormone balance in the latter part of pregnancy (lowered progesterone and presence of free estrogen) is apparently released from the inhibition exerted by its hormonal antagonists, progesterone and pitocinase. Increase in desoxycorticosteroids late in pregnancy, aided by salt, sensitizes the smooth muscle of vessel walls and probably that of placental vein sphincters to increased reactivity. Spasm of the venous sphincters obstructs exit of fetal blood from the corresponding placental units, causing distention of villous capillaries, enlargement of villi, diminution or obliteration of the intervillous spaces and circulation, resulting in anoxic necrosis of chorionic epithelium, villous stroma, and capillary endothelium.

Thromboplastin, abundant in placental tissue, is apparently the first product of chorionic necrosis, which, if infarction is extensive, causes abruptio by subplacental clot formation and occasionally afibrinogenemia with hemorrhagic tendency. It is apparent that there is only one true toxemia of pregnancy—that due to placental infarction and necrosis. It comprises abruptio placentae, eclampsia, and its precursor, preeclampsia. Other conditions presently included in the accepted classification of toxemias of pregnancy constitute predisposing causes rather than types of toxemia. It is hoped that biochemical study of normal and toxic placentas and blood, now in process, may serve to identify the nature and effects of other degradation products of placental necrosis, which are probably more concerned with preeclampsia and eclampsia.

PEDIATRICS

The Nephrotic Syndrome in Early Infancy: A Report of Three Cases. H. McC. Giles, R. C. B. Pugh, E. M. Darmady and others. Arch. Dis. Childhood 32:167-180 (June) 1957 [London].

Renal changes were manifest in 3 newborn infants. Two of them were siblings, and both sets of parents were first cousins. Each infant showed a similar abnormality of the renal tubules on microdissection, doubly refractile crystalline material in alcohol-fixed tissues, and predominant lesions in the renal tubules with probably secondary glomerular damage. The severity of the histological changes was correlated with the presumptive duration of the illness. The findings suggested that all 3 infants had the same genetically determined primary disorder. A review of previously reported cases of the nephrotic syndrome in newborn infants shows that the most common feature, apart from the essential clinical and biochemical similarities, was an invariably fatal outcome, usually in the first 6 months of life. Parental consanguinity has not previously been reported. The inherited defect in the 3 infants may be manifested by an anomaly of the renal tubules and by the deposition of anisotropic crystalline material in certain tissues.

Vaccinia Gangrenosa and Agammaglobulinaemia. K. Somers. Arch. Dis. Childhood 32:220-224 (June) 1957 [London].

A 6-month-old male infant with vaccinia gangrenosa is described. The progressive necrotizing vaccinal reaction, failure to heal, the development of gangrene, and appearance of fresh lesions at various sites were distinguishing features of vaccinia gangrenosa. Plasma protein studies revealed agammaglobulinemia. Virological studies confirmed the presence of vaccinia; there was a secondary micrococcic (staphylococcic) infection. The patient had no humoral defenses against the virus, perhaps because of gamma globulin deficiency. He was, thus, a perfect medium for the cultivation of vaccinia virus, which produced gross cutaneous and visceral damage. The baby was given various antibiotics and intramuscular injections of vaccinia gamma globulin, but without result. The disease, at autopsy, was characterized by lymphoid atrophy, absence of healing, and poor inflammatory response. Patients with agammaglobulinemia should not be vaccinated. Those with generalized vaccinal reactions should be examined for gamma globulin.

Does Celiac Disease Really Exist? With Reference to 16 Personal Cases. M. Jeune, R. Carron, M. Flattot and G. Lafond. Semaine hôp. Paris 33:2459-2475 (June 22) 1957 (In French) [Paris].

The existence of celiac disease is still disputed by some authorities in spite of the many works that have recently been published on the subject and in spite of the fact that gliadin has been shown to act as a precipitating agent in causing it. The authors, however, believe that such a disease unquestionably does exist, and they cite the cases of 16 patients seen by them in the last 4 years. A valid diagnosis of celiac disease was established in each case. The disease, which is characterized by the chronic elimination of steatorrheic stools in excessive quantities, a distended abdomen, and arrested growth in weight and height, is due primarily to intolerance for certain constituents of certain flours, can be explained either mechanically (increased physiological cleansing processes in the presence of mucosal sensitivity), or allergically (mild sensitization).

In the asthma of millers degenerative processes, produced mechanically by dust, generally predominate; these in turn bring on chronic bronchitis, asthma, or emphysema. Cutaneous tests produce no reaction, and rhinitis is absent. Allergic factors, in addition to the mechanical action of dust, seem to play a causal role in the asthmatic bronchitis of a small number of patients with millers' asthma. The cutaneous tests may be positive in these patients. The literature reports cases of purely allergic asthma in millers, being due to flour, bran, or extraneous admixtures, but the author did not observe cases of this type. He admits, however, that he made no cutaneous tests with bran; but the 8 millers gave no indications that their disorder involved processes analogous to those that play a part in the allergic asthma of bakers. He believes that his studies demonstrate that the unitarian concept of the allergic origin of bakers' asthma and of millers' asthma applies only under certain conditions, if at all. It must be emphasized, however, that occupational factors play a part in the forms of bakers' and of millers' asthma under consideration here. Although the cause may differ in the asthma of bakers and millers, both disorders are definitely of occupational origin.

Vitamin B_{12} in Acute Subdeltoid Bursitis. I. S. Klemes. Indust. Med. 26:290-292 (June) 1957 [Chicago].

In 1953, the author had reported on 6 patients with subdeltoid bursitis in whom large doses of vitamin B_{12} (1 mg. per dose) produced rapid relief. Roentgen examination revealed absorption of the calcium deposits. Since then, 40 additional patients have been treated successfully, sufficient to indicate that such use of vitamin B_{12} is an effective therapy in acute subdeltoid bursitis. This newer material is presented. The simplicity of administration, the virtual absence of side-effects, and the results obtained merit further clinical trial and controlled study.

Breathless Coal Workers as Seen at the Golden Clinic. J. E. Martin Jr. A. M. A. Arch. Indust. Health 15:494-498 (June) 1957 [Chicago].

Physical examinations, roentgenograms of the chest, and respiratory function studies made in 207 soft-coal workers who came from northeastern West Virginia, southwestern Pennsylvania, and western Maryland and were admitted to the Golden Clinic in Elkins, W. Va., revealed a disease identical with or very similar to coal workers' pneumoconiosis as described by British investigators. The classification of the pneumonoconiosis research unit of the Medical Research Council of England could be readily applied to the roentgenograms of the chest obtained from the American soft-coal miners. These miners were treated for their respiratory difficulties with intermittent positive-pressure breathing combined with administration of nebulized isoproterenol (Isuprel) hydrochloride over a period of about 20 minutes. Eight drops (0.5 cc.) of a 1:200 solution of the drug mixed with 8 drops of water were nebulized. Two to 4 or more of such combined treatments were given daily.

Twenty of the 207 patients showed a decrease in maximal breathing capacity (expressed as per cent of pretreatment maximal breathing capacity, per cent of estimated normal) and the remaining 187 showed increases in maximal breathing capacity from 1 to 80% or more. Ninety-four (45%) showed significant increases of more than 30% in maximal breathing capacity. Cyanosis disappeared and dyspnea, wheezing, and cough lessened. The character and amount of sputum changed. Appetite improved. The patients often gained weight during their hospitalization. Improvement lasted for a few days to many months. Usually, symptoms returned or were markedly accentuated after an acute respiratory infection. Side-reactions to this type of treatment were few. Some patients complained of increased nervousness and palpitation, but these complaints were almost always prevented by nebulizing the isoproterenol at a slower rate. Diffuse chest pain, which occurred in the early days of the treatment, almost always disappeared with continued treatment. It appears that intermittent positive-pressure breathing with isoproterenol is a safe and effective means of therapy in chronic respiratory difficulties.

THERAPEUTICS

Cortisone and Syphilis: Results of Preliminary Corticotherapy in Penicillin Treatment of 120 Patients with Syphilis. P. de Graciansky and C. Grupper. Rev. Franç. études clin. et biol. 2:579-594 (June) 1957 (In French) [Paris].

Since 1951, the authors employed the rapid therapy of syphilis with massive doses of penicillin. They investigated systematically what aid corticotherapy in the form of cortisone, hydrocortisone, or corticotropin could provide in the various problems involved in this type of treatment. The 120 patients treated over a period of 5 years included patients with the various forms and stages of syphilis. At first the authors employed cortisone either by intramuscular injection or by mouth for 5 or 8 or even 30 days before the onset of penicillin therapy. Later, in 101 of the 120 patients, hydrocortisone was used. Infusion of corticotropin was tried in 2 patients, but this treatment was discontinued, because similar results could be achieved with the more simple forms of administration. Local corticotherapy was used in interstitial keratitis (instillation or subconjunctival injection) and in arthropathic tabes (intra-articular injection).

Preliminary cortisone therapy prevented or diminished in most patients the clinical signs of Herxheimer's reaction, particularly the fever response, in the early as well as in late forms of syphilis. Cortisone therapy also modified the clinical manifestations of syphilis. Variable improvements were noted in the primary lesion, in the secondary syphilides, in the gummas of the skin and of the mucous membranes in tertiary syphilis, in some subjective symptoms of neurosyphilis, and in interstitial keratitis. Cortisone therapy significantly reduced the biological signs of the syphilitic process: the Treponema organisms either disappeared or declined in number; there was a fall in the concentration of reagin in primary and secondary syphilis and in tertiary syphilis accompanied by clinical lesions, and abnormalities of the cerebrospinal process subsided. By contrast, in the purely serologic specificities there was no modification in the reagin concentration when it was low, as for instance in the so-called irreducible Wassermann reaction. Cortisone therapy did not diminish the sensitivity of the Treponema organisms to penicillin. nor was the usual course of syphilis after penicillin therapy altered by the preliminary cortisone therapy. Cortisone is a useful adjuvant in certain tabetic manifestations (lightening pains and gastric crises) and in interstitial keratitis. Cortisone increases the tolerance to penicillin in allergic subjects, in pregnant women, and in patients with syphilitic aortitis and with neurological syphilis.

Therapy in Collapse Due to Meningococcus Infection. J. E. Cassidy. Ann. Int. Med. 46:1099-1104 (June) 1957 [Lancaster, Pa.].

Of 63 patients with acute meningococcic infection who were given antibacterial therapy with sulfadiazine and crystalline penicillin G combined with the administration of such agents as desoxycorticosterone acetate, cortisone, corticotropin, norepinephrine, epinephrine in oil, plasma albumin, and nikethamide (Coramine), 3 progressed from mild toxemia to severe shock; of these, 1 died as a direct result of collapse, with adrenal hemorrhage, and another died of massive gastrointestinal bleeding, with associated adrenal hemorrhage observed at autopsy.

The danger of acute collapse exists in every acute meningococcic infection. Successful treatment requires immediate institution of adequate antibacterial therapy, the most satisfactory being a combination of sulfonamide and penicillin by available routes. with anticipation of adrenocortical failure and overwhelming toxemia by immediate administration of hydrocortisone intravenously at the rate of 300 mg. per 24 hours to all patients with meningococcic meningitis and/or meningococcemia. Collapse did not occur in 18 patients who were treated in this manner after admission to hospital. With return of the temperature toward normal, cessation in formation of cutaneous lesions, return of consciousness, and stabilization of blood pressure, cortisone by oral or intramuscular route was substituted. The dose was then tapered gradually to prevent "rebound" phenomena and to exclude the possibility that exogenous steroid had masked significant adrenocortical destruction. Levarterenol therapy of patients in collapse (if it occurs before specific therapy has succeeded) has proved life-saving. Three additional patients admitted in collapse were saved in this way.

Hydrocortisone may be more desirable than cortisone because of its more direct metabolic effect. The essential step is to produce a level of circulating hormone so rapidly that it is available in event of any adrenocortical damage. In addition to this, the anti-inflammatory or antitoxic effect of this substance is also important in reducing the fatal potentialities of the disease. Once collapse has occurred. steroid-antibiotic therapy alone may be inadequate. Here the pressor amines find specific usefulness. With these. the patient admitted to treatment in shock may be sustained long enough to give the former specific drugs an adequate opportunity. The combination of levarterenol and steroids seems to be synergistic in reversing collapse.

Butazolidine Treatment in Thrombophlebitis. H. Høst. Tidsskr. norske lægefor. 77:423-424 (May 15) 1957 (In Norwegian) [Oslo].

In department 8, Ullevål Hospital, 25 patients with thrombophlebitis were treated with Butazolidine. The response was good in 14 of the 17 cases of superficial thrombophlebitis. The impression is that in several of the 8 cases of deep thrombophlebitis the pain decreased as a result of the treatment. The average daily oral dose was 400-600 mg. for from 3 to 7 days. From 1 to 3 injections of 600 mg. were given intramuscularly at 2-or-3 day intervals. In some cases an intramuscular injection of 600 mg. was given the first day, followed by peroral treatment for a couple of days. The average duration of treatment was 5 days. Exanthem, which occurred in 2 patients, disappeared after 3 or 4 days. No other complications were observed. In superficial thrombophlebitis Butazolidine must be given for only a few days and under close supervision. Tendency to edema, ulcer, and allergic reactions are regarded as absolute contraindications.

BOOK REVIEWS

Clinical Cardiopulmonary Physiology. Sponsored by American College of Chest Physicians. Editorial Board: Burgess L. Gordon, M.D., and others. Cloth. $15.75. Pp. 759, with 248 illustrations. Grune and Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1957.

This monograph was planned to present normal cardiopulmonary mechanisms and their disturbances in diseases of the chest. The first chapters deal with normal physiology and are followed by chapters covering methods of examination and testing of cardiopulmonary functions. Succeeding chapters discuss the clinical physiology of impairment of the mechanics of respiration, obstructive phenomena of the respiratory tract, and mixing and dilution problems of the alveolar membrane, with adequate consideration of common and less common pulmonary diseases. The last chapters are devoted to the pathophysiology of cardiovascular diseases of the chest and include considerations of cor pulmonale, pulmonary edema, acquired valvular heart disease, congestive heart failure, congenital malformations of the heart, and impairment of the pulmonary circulation. While the emphasis throughout is on the physiology and pathophysiology of cardiopulmonary disease, etiology, pathogenesis, treatment, and prognosis are capably discussed.

The editorial committee of the College of Chest Physicians has succeeded in its aim of integrating basic data with the medical history and the physical examination and of combining the thinking of laboratory and bedside investigators of cardiopulmonary physiology and pathophysiology. As may be expected from multiple authorship, there is some unevenness in the quality of presentation. Thus, some parts of the chapter on the mechanics of breathing are difficult to follow and, contrariwise, the chapter on cor pulmonale is exceptionally lucid. There are a few errors. Hydrogen ion concentration and pH are confused in the discussion of respiratory acidosis on pages 10 and 11; hemoptysis is a sign rather than a symptom (page 61); the dosage but not the name of an antibiotic is given on page 458; and figures 13 to 18 on pages 604 to 608 follow the corresponding text by several pages. Occasional typographical errors were also noted. The monograph is recommended to physicians specializing in medicine and/or surgery of the chest and to interested general practitioners, internists, and general surgeons.

Fundamental Marriage Counseling: A Catholic Viewpoint. By John R. Cavanagh, M.D. Special chapter by Alphonse H. Clemens, Ph.D., and others. Cloth. $8. Pp. 598, with illustrations. Bruce Publishing Company, 400 N. Broadway, Milwaukee 1, 1957.

This learned volume presents the substance of the thinking of four physicians, a judge in the United States District Court in the District of Columbia, several Catholic theologians and chaplains, a sociologist, and others. There is an extensive glossary and list of references. There is no mincing of words or phrases even when the discussion seems to be non-Catholic or against prevailing thought. The facts are set down scientifically and are taken from authoritative sources. The entire text is well documented. A few diagrams and tables are included to clarify the text. The chapter on heredity is of special interest. Heredity of acquired characters is denied, and the information on germ cells and body cells is up to date, accurate, and complete, thus providing a sort of refresher course for those who are not conversant with the latest concepts. Five sections are devoted to such matters as the biological aspects of marriage, its sexual aspects, fertility and marriage, and social and religious aspects of marriage. Concerning artificial insemination, it is emphasized that this subject is fraught with dangers and limitations. Contraception is fully discussed and disallowed, but the rhythm method may be permitted under special circumstances as regards the health of parents and socioeconomic conditions. In each case the moral law is paramount, and wise counsel must be obtained from the physician, priest, or prelate. Counseling in marriage should begin with the engaged couple seen separately and together. Nothing can be hidden; each party must know the exact mental and physical status of the other. After marriage, in the first months, the counselor may be called on to straighten out difficulties and dangers and thus make the marriage work. Such a counselor must be learned in civil and moral law and in science, medicine, sociology, and economics. This seems too much to ask, but if one is really in earnest and wishes to give the best possible advice to inquirers, he would do well to study this volume.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

RADIATION EXPOSURE DURING DENTAL EXAMINATION

To the Editor:—*Recently increasing concern has been shown regarding the hazards implied in the use of diagnostic as well as therapeutic x-rays. What is an opinion as to the x-ray dosage to which routine dental films expose the patient in the average office, and what significance, if any, is there to the repetition of these dosages at nearly every subsequent visit to the dentist (ordinarily recommended to be twice a year) over the average lifetime? Also, are there any figures as to the ratio, in these exposures, between the dose received by the head and neck and the dose received by the gonads in the two sexes? Would the latter dose be considered significant from a genetic standpoint?*

Alfred B. Mason, M.D., Concord, Calif.

Answer.—The amount of radiation received by the patient during a routine dental roentgenographic examination depends on a number of factors. The type of equipment, the speed of the film, the technique employed, and, for certain considerations, the physical size of the patient determine the amount of radiation necessary to obtain a satisfactory roentgenogram. Depending on these variables, the radiation may vary from the high figure of 315 r per 70 seconds for full-mouth examination as cited by Nolan and Patterson (*Radiology* 61:625, 1953) to as low as 0.24 r per two-second exposure as reported by Yale and Goodman (*J. Am. Dent. A.* 54:354, 1957). A reduction to one-thirtieth of the unfiltered dose was attained by interposing 0.375 mm. of copper and 0.5 mm. of aluminum in the primary beam of the conventional dental x-ray machine without affecting the excellence of the roentgenograms. Such use of proper filtration and other means of dose reduction are rapidly becoming standard practice in dental radiography.

A conventional dental roentgenographic examination consists of 14 films. The exposure to the gonads of the patient who receives one such examination annually from age 10 to age 30 would be approximately 0.3 r for the male and about 0.05 r for the female. The natural background radiation to which everyone is exposed is about 4 to 5 r for a 30-year period. All radiation is significant from a genetic standpoint. The amount of gonadal radiation received incidental to dental radiography is but a fraction of the natural background radiation, however, and would appear to be relatively insignificant.

DETECTION OF BREAST CANCER

To the Editor:—*Is information available concerning the chemical product heptaldehyde for specific use in detection of cancer of the breast?*

L. F. Valentine, M.D., Santa Monica, Calif,

Answer.—Work is currently being done on temperature changes of the skin in cases of cancer of the breast (Lawson and others: *Canad. M. A. J.* 75: 486, 1956). The substance referred to is not recommended for therapy; its use is strictly experimental, since present knowledge about its pharmacology is still quite inadequate.

STERILIZATION OF ELECTRIC RAZORS

To the Editor:—*The advisability and feasibility of using electric razors for shaving patients in a psychiatric hospital of about 1,100 patients are being considered. How great is the need for sterilizing an electric razor before use on each patient? What quick method of sterilization can be used which would not be too time consuming and yet would be adequate and safe from a bacteriological standpoint? Could this procedure be applied to all existing models of electric razors or to only a specific make?* *M.D., Massachusetts.*

Answer.—The procedure of sterilization could be applied to all existing models of electric razors, inasmuch as the heads of most razors are easily removed and the combing and cutting surfaces are rendered accessible. However, unless there is an obvious "sore" or open lesion on the face of a patient, all that would be necessary would be to follow a specific routine of cleaning the razor with a brush, an antiseptic soap or detergent, and running water between each usage. Additional cold sterilization would offer no great advantage. However, in the presence of infection, the best and safest measures would include either boiling the razors in a lye water or, preferably, autoclaving them for 15 minutes under 15-to-20-lb. pressure. If untrained help are being used for this task, a simple procedure should be outlined and adhered to, so that the process of sterilization becomes standardized.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

the patient for several months wear only shoes with a flannel box toe and without any materials derived from rubber. If this does not bring relief, the dermatologist must then tackle the formidable problems of dermatological differential diagnosis of foot dermatoses and, if necessary, proceed to search for causal allergens among the hundreds of different materials—dyes, mordants, tanning agents, polishes, etc.—which are present in socks, stockings, shoes, and other footgear.

FORMALDEHYDE DERMATITIS

To the Editor:—*Please supply information regarding cases of dermatitis of the hands produced by the product Celeron.*

Albert Rubin, M.D., Hartford, Conn.

Answer.—Celeron is a phenolic-formaldehyde resin. Dermatitis from this class of substances is chiefly associated with the formaldehyde component. Formaldehyde as such in its gaseous state, in the aqueous solution formalin, and as it appears in unpolymerized form in various resins and plastics is a ready sensitizer. Although it is linked with phenolics which may be harmful to the skin, formaldehyde nearly always proves to be the offender. Patch tests utilizing this form of synthetic resinous product, applied to persons uninvolved in the dermatitis, usually are negative; such tests, however, are undesirable because of their readiness in provoking sensitization. In the case of persons already involved in dermatitis from formaldehyde, there is frequently a severe reaction to patch testing. So active are some phenolic-formaldehyde resins that on occasion retention of some of the formaldehyde compounds on a worker's clothing is sufficient to sensitize members of his family at home. A mild case of formaldehyde dermatitis will disappear without treatment, once the person is removed from exposure. With or without treatment, the dermatitis is likely to persist or to recur if there is reexposure.

INCREASED SEDIMENTATION RATE

To the Editor:—*Are antibiotics indicated in patients in whom the only abnormal findings, clinical or laboratory, are increased sedimentation rates? There are no subjective complaints, and the physical examinations performed as a health audit are completely normal.* *Daniel Haffron, M.D., Elgin, Ill.*

Answer.—The word "patients" is used in the query, but the statement implies that health audits were made of normal persons. It would be important to know if the sedimentation rates were slightly or greatly increased. There is no reason for antimicrobic therapy in a healthy person whose only abnormality is an increased rate of sedimentation of erythrocytes. Slight deviations in both directions occur transiently or permanently, probably dependent upon relative amounts of globulin and albumin in the blood of otherwise normal persons, just as the average body temperature and the number of erythrocytes and leukocytes vary within a normal range. The rate may be increased by anemia, menstruation, and pregnancy. It is said to be slightly faster in women than in men.

ANTIBIOTICS WITH VITAMIN C

To the Editor:—*Is there any evidence that vitamin C potentiates the effect of penicillin in treating streptococcic infections?*

Ralph L. Gorrell, M.D., Clarion, Iowa.

Answer.—There is no known evidence that vitamin C potentiates the effect of penicillin in the treatment of any infection. The proposal has been made that vitamin C might bring about more efficient absorption, and thus higher blood concentrations, of tetracycline. A study just completed of this combination shows no potentiating effect of vitamin C on tetracycline. There are several preparations that contain ant biotics and a variety of vitamins—the so-called "stres formulae—and vitamin C is included in such prepar tions. There is no evidence that these vitamin con binations potentiate the activity of the antibiotic i volved, although they may be of indirect value whe there is an actual vitamin deficiency.

EATING GOOSE EGGS

To the Editor:—*Is there any scientific evidence th there is danger in eating goose eggs?*

M.D., New York.

Answer.—This consultant is unaware of any repor indicating that goose eggs are less nutritious tha chicken eggs. Goose eggs tend to have a slightl higher fat content than do chicken eggs, but differ ences in amount of protein are not marked. The reaso for the somewhat higher fat content is due in part t the lower water content. A chicken egg will run abou 75% water, while the goose egg contains about 60 water. As far as is known, fresh eggs of almost an species of fowl, when properly prepared, can be con sidered a highly nutritious food and are not known t cause any definite diseases.

PERSISTENT PAIN AFTER HERNIA REPAIR

To the Editor:—*I was interested in the query in The Journal for June 22, 1957, page 942, regarding persistent pain after hernia repair. I have seen sever of these patients, and, when there are no ment symptoms, the local injection into the painful are of 1 or 2 cc. of a 1% or 2% solution of quinine an urea hydrochloride will usually give relief from th pain in the postoperative scar. The injections ar usually repeated once a week for five or six time Procaine and Pyribenzamine have proved ineffecti in my experience.*

WASHINGTON NEWS

FROM THE WASHINGTON OFFICE OF THE AMERICAN MEDICAL ASSOCIATION

Active Session in Health Forecast . . .
Asian Influenza Group Appointed . . .
Report New High in Rehabilitation . . .
VA Medical Advances . . .
Civil Defense Hospital Units . . .

FOGARTY SEES ACTIVE SESSION ON HEALTH

Rep. John Fogarty (D., R. I.) a leading advocate of federal aid for medical research and other health programs, foresees increased activity in the health field during the next session of Congress. He places high on the list bills for federal construction aid to medical schools, including his own proposal introduced last May.

The administration has indicated it will push for this legislation, too. In an address to the American Hospital Association meeting in Atlantic City, N. J., the chairman of the important House appropriations subcommittee on health, education, and welfare, touched on the following:

Government in health—"It is now generally accepted that the health of our people is a major national resource and that the government, therefore, has a direct responsibility for the health of everyone."

Hospitals as health centers—Within the next 25 years, virtually every general hospital in the U. S. will be providing at least as much preventive service as curative service. "You are, in fact, moving closer each moment to the day when hospitals will be the focal point of health services for all of us throughout our entire lives."

Broadening Hill-Burton—The Hill-Burton hospital-clinic program, while "tremendously successful in aiding the growth health resources," cannot continue indefinitely to retain the limits of the present pattern of operation. "I would urge you to think in terms of developing new proposals to meet future needs with the aid of the basic Hill-Burton legislation."

Comprehensive health insurance—The single greatest need is for a "one-package" policy combining both prepaid medical care and hospital insurance, with encouragement of preventive medical care and periodic health examinations. On catastrophic insurance, policies should not be hedged with cancellation clauses, and premiums can be increased during the more productive years to offset the increased risk of coverage after retirement.

Mr. Fogarty says it is now generally accepted that the health of our people is "a major national resource and that the government, therefore, has a direct responsibility for the health of everyone." In addition, he feels that federal funds should be used to stimulate expenditures of funds from the states, communities, and private sources.

The AHA made Mr. Fogarty an honorary member of the association. A year ago Sen. Lister Hill (D., Ala.), co-author of Hill-Burton, was given similar recognition.

ADVISORY COMMITTEE NAMED ON ASIAN INFLUENZA

As autumn brings closer the season when influenza generally reaches its highest incidence, these were the developments on the situation in Washington, D. C.:

1. The Public Health Service announced appointment of a technical advisory group representing medical schools and state and federal medical leaders to "assist PHS in appraising the current status of influenza research and planning how to meet future research needs in this field."
2. Cases, as estimated by the PHS on the basis of incomplete reports from state health officers and military sources, continued to rise, with prospects for a total of half a million in October.
3. A total of 10,669,091 doses of vaccine had been released by the Public Health Service before Oct. 1. The latest release of 3,712,059 cc. included 2,154,309 for civilian use and 1,557,750 for military. The vaccine is distributed to states according to their population.

Surgeon General Burney said the advisory committee would help determine whether some aspects of influenza research are receiving inadequate consideration and also act as "a point of liaison" for influenza research activities within PHS and the military services.

Dr. James A. Shannon, head of the National Institutes of Health, will have general responsibility for meetings of the group, which held its first session Sept. 27. Members, as announced by PHS, are as follows:

Drs. George E. Burch, professor of medicine, Tulane University School of Medicine, New Orleans; Edward C. Curnen Jr., professor of pediatrics, University of North Carolina School of Medicine, Chapel Hill; Gail Dack, director of food research institute, University of Chicago; Fred M. Davenport, School of Public Health, University of Michigan, Ann Arbor.

Drs. Dorland J. Davis, scientific director, National Institute of Allergy and Infectious Diseases; Geoffrey T. Edsall, director, division of communicable diseases, Walter Reed Army Institute of Research;

Keith Jensen, Public Health Service Laboratories, Montgomery, Ala.; Capt. J. R. Kingston, U. S. Navy, general medicine and surgery branch, research division, Navy; Dr. Robert F. Korns, New York State Department of Health, Albany, N. Y.

Drs. Alexander D. Langmuir, chief, epidemiology branch, Communicable Disease Center, Atlanta, Ga.; Colin M. MacLeod, professor of experimental medicine, University of Pennsylvania School of Medicine, Philadelphia; Col. Thomas W. Mattingly, chief of cardiology, Walter Reed Army Medical Center, Washington, D. C.; Thomas F. Sellers, director, Georgia Department of Public Health Laboratories, Atlanta, Ga.; Joseph E. Smadel, associate director, National Institutes of Health, PHS.

Earlier Dr. Burney had written the six manufacturers of vaccine, urging them to allocate their output in line with priority recommendations of state and local advisory committees. In general priorities call for vaccination first of people in the health professions, those whose condition makes them a high medical risk, and those needed to maintain essential community services.

A spokesman for one of the manufacturers said his firm would attempt to comply with the PHS request, but that there were limits to the amount of allocating that could be done by the producers, except for shipping to states on the basis of population.

He noted that only a relatively small portion of the manufacturers' output is shipped directly to physicians and other high priority users. Most goes to wholesalers, many of whom sell directly to physicians as well as to retail druggists. This manufacturers' representative said the wholesalers might be in a better position to observe state and local priorities, particularly if they cooperate closely with advisory committees.

VA ANNOUNCES ADVANCES IN MEDICAL TREATMENT

The Veterans Administration announces these advances in medical treatment of patients at its hospitals:

At the Hines, Ill., Hospital, researchers have adopted a concrete industry idea to develop a technique that utilizes ultrasonic waves to test the extent of bone fractures and the degree to which they have healed.

Says VA: "Preliminary studies have shown that this technique offers an objective and accurate method of analyzing the degree of healing, helping in the reduction of bed stay for hospitalized veterans."

The concrete industry uses a somewhat similar ultrasonic method of testing the quality of concrete slabs and blocks.

Dr. Eugene J. Towbin of the VA hospital in Little Rock, Ark., reports isolation of a new anti-blood clotting substance that may have value in treatment of heart and blood vessel diseases. He said the new anticoagulant may be of a type that will not produce undesirable reactions, but it will have to be purified and chemically identified before it can be determined whether the substance will be of value in actual treatment of patients.

FCDA SETS REGULATIONS FOR STORAGE OF EMERGENCY HOSPITALS

In an advisory bulletin, the Federal Civil Defense Administration instructs state and regional civil defense officials on how emergency hospital units should be stored, "so that the greatest number will be at, or as close as possible, to the place of eventual use."

The bulletin outlines requirements for location, storage, and maintenance and includes a sample form of storage agreement. It says in part:

"The Federal Civil Defense Administration is now procuring and stockpiling in its warehouses throughout the United States, medical supplies, including Civil Defense Emergency Hospital units, for use in case this country is attacked. While the above procedure is in process, there must, in addition, be a more widespread and strategic distribution of hospital units so that the greatest number will be at, or as close as possible, to the place of eventual use.

"This distribution plan requires the safe, permanent storage of a hospital unit in unopened original containers at or near an appropriate facility where it could be unpacked and put into operation at time of emergency, in the least possible time. Such a manner of storage is defined as prepositioning."

Because of present limited supplies of the emergency hospital units, they are now being allocated on the basis of one per 100,000 of population in metropolitan target areas. As more hospitals are purchased by the U. S., the allotments will be increased.

In selecting sites for storage of the hospitals, FCDA advises that particular consideration be given to exits, doorways, stairways, and weight limits. Total weight of unit is 12 tons, it includes 367 cases, and occupies 1,606 cu. ft. Seventy-one cubic feet of heated storage are required, and 9 ft. of flammable and the same amount of cold storage.

Recommended locations are between 15 and 30 miles from the target centers.

"MISSING STEP" EXPLAINS MAN'S INABILITY TO PRODUCE VITAMIN C

Scurvy may be caused by a "missing step" in the human body's operation that prevents the production of vitamin C, according to a Public Health Service researcher, Dr. J. J. Burns, a biochemist at the National Institute of Health.

The enzymatic step missing in man, monkeys, and guinea pigs is found in all other animals, Dr. Burns says. Its absence was uncovered by tracing similar amounts of L-gulonolactone administered to rats and guinea pigs. Previous work had established that L-gulonolactone is a forerunner of vitamin C in the liver of the rat, which can manufacture its own vitamin C. These tests demonstrated that, while rats converted L-gulonolactone into vitamin C, guinea pigs did not.

Dr. Burns' research is described by him in the British journal *Nature*.

INITIAL TREATMENT OF BURNS IN MASS CASUALTIES

Kent L. Brown, M.D.
and
Donald M. Glover, M.D., Cleveland

THE management of mass burn casualties has acquired new importance with increased industrial hazards and the potential use of atomic weapons. Hospitals and emergency wards are generally unprepared to meet these overwhelming situations. We found that a few patients with extensive burns completely engaged the personnel and much of the working space in a well-equipped emergency room in a 500-bed hospital. In one instance, two patients with extensive burns, treated at the same time, tied up all emergency room personnel and four additional persons from other divisions for a period of two hours. It is obvious that a large number of patients would have to be handled in a different manner if they were to receive any reasonable emergency treatment. In a major disaster, the patients with very severe burns and minor burns would be eliminated by careful sorting to give the largest number of persons with severe but treatable burns a chance for initial care and survival.

A few patients with extensive burns can completely engage the personnel and much of the working space of the emergency room of a hospital. A large number of patients have to be handled in a different manner if they are to receive any reasonable emergency treatment. Sufficient space to handle many casualties within minutes or hours is an absolute requirement for any hospital. Under disaster conditions, practically all burned patients should receive prophylactic antibiotics. Where time is important, supportive therapy for extensive burns must be emphasized and a predetermined standardized procedure employed.

The philosophy in dealing with mass burn casualties is not different from that in handling mass war injuries. The objective is to give primacy in treatment to those individuals most likely to survive their trauma. It is evident from our experience and from the experience of those institutions which have been confronted with burn disasters that a large number of burned persons could never be crowded into the average hospital emergency room. It is further evident that hospitals, for the most part, would be inadequately implemented with equipment and supplies for treatment of large numbers of patients.

Although St. Luke's Hospital has never been faced with a burn disaster, we recognize the importance of a well-formulated program should such an event occur. The plan we suggest emphasizes organization of hospital personnel, stockpiling of

liter of water is a satisfactory mixture. Sodium chloride in dextrose, sodium lactate, Ringer's solution, or Ringer's lactate solution may be used.

Closed Method of Treatment.—When immediate treatment is given by closed methods, a simple technique will expedite coverage of the burn. Large surfaces may be covered quickly with gauze freshly dipped in petrolatum (fig. 2*F*) before the occlusive dressing is applied. If the patient is not in shock and can stand, even more time is saved. Adherent foreign materials are removed, but vesicles are not opened. The dipping mixture, which is stored in drums or gallon cans at room temperature, is a combination of 30% amber petrolatum and 70% liquid petrolatum. The latter ingredient should be medium heavy. The stainless steel dipping pan is 4 in. deep and 14 in. square. In the center, 1 in. from the bottom, is a steel rod 1 in. in diameter which runs the length of the pan.

Rolls of fine mesh gauze 1 yd. wide are cut in 9-in. lengths and kept sterile. These rolls are saturated in the mixture by unrolling them beneath the steel rod and passing the gauze back and forth until it is soaked. Then strips of suitable length are cut to cover large surfaces. These strips are always applied vertically to the long axis of the body or extremity. A single prefabricated dressing 18 in. square and 1 in. thick will cover a large part of the front or back. Two can be rolled to cover an extremity. These are held by wrapping uniformly with Ace bandages, rolled gauze, or rolled crepe paper. Prefabricated dressings are made up of fine mesh gauze on one side and a paper cover on the other. The padding may be cotton, sheet wadding, Cellucotton, or mechanics waste. The sterile dressings are wrapped individually and stored. If this method is not practicable, gauze previously prepared with petroleum jelly or bismuth tribromphenate (Xeroform) or plain fine mesh gauze, dry, may be substituted. If necessary, the prefabricated dressing can be applied directly to the burned surface.

Open Method of Treatment.—The open air or exposure method is applicable when warmth and shelter are available, when transportation is not required, where burns are in suitable regions of the body, and where there are overwhelming numbers of burns. Often cradles are not available. In this emergency, upright poles can be fastened to the bed and a rope strung between them (fig. 2*G*). A sheet can be draped over the rope like a tent.

Adjuncts to Treatment.—Morphine is administered sparingly to patients in shock and should be given slowly intravenously. Judicious use of barbiturates will help allay apprehension and decrease the amount of narcotic required. In time of disaster, a tetanus toxoid booster dose or tetanus antitoxin should be given to all burned patients. Patients should be tested for serum sensitivity before administration of antitoxin.

Under disaster conditions, practically all burned patients should receive prophylactic antibiotics. Penicillin is preferred for parenteral use. Other broad-spectrum antibiotics may be used orally. It is imperative that patients to be transported receive prophylactic antibiotics. Patients treated in general hospitals need no antibiotic during the first 24 hours, but the use of antibiotics should be started during the second 24 hours on all who have indwelling catheters. This period gives time to eliminate patients with histories of allergy to antibiotics. The use of corticotropin (ACTH) and cortisone should be avoided except under controlled conditions.

Regardless of the method of treatment of the burned area, tracheotomy should be performed when required in extensive face or neck burns. It is also advised at earliest indication where fire has been inhaled with resultant pulmonary burns.

Ionizing Radiation.—While exposure to ionizing radiation should be recognized and recorded, patients so exposed do not ordinarily require immediate treatment. Those patients within the zone receiving 600 r or more will probably die and should be assigned to group 3, which is the category of fatal burns. Persons receiving 400 r to 600 r are assigned to group 2 where they will be treated. About half will be savable. These patients require antibiotics and, in certain instances, supportive therapy. The casualties receiving less than 400 r are handled as group 1 patients in the burn grouping. They are sent to secondary centers for observation. In burns due to irradiation, skin changes will appear late.

Disposition.—It should be noted that persons with burns complicated by other injuries may be under simultaneous treatment by other teams. In the case of a large disaster, the receiving hospital may not be able to keep all of the casualties. In that event, transportable burned patients who have been given initial care are evacuated to other centers.

Summary

A method of management of mass burn casualties is needed for efficient and rapid disposition of patients by a minimum of personnel. Planning for organization, space utilization, sorting, immediate treatment, and preparation for definitive care is important. It is hoped that these suggestions will serve as a stimulus toward a tentative plan or organization which may easily be modified to meet the requirements of each local situation.

DERMATOLOGICAL RADIATION THERAPY IN THIS NUCLEAR AGE—AN APPRAISAL

Paul M. Crossland, M.D., Santa Rosa, Calif.

The need for radiation therapy in dermatology has been greatly reduced by recent developments in pharmacology and endocrinology. Striking successes with the use of antibiotics and steroids have led to the abandonment of radiotherapy in many diseases. In others, its use has been rendered more precise by new advancements in radiology. Irradiation of the skin can be more closely confined to the disease process by choosing the proper half-value layer from the zone of soft roentgen rays, by the use of beta-emitting radioactive isotopes, and by shielding. Dermatological radiation therapy is localized, the doses are minimal, and the exposure is fractionated. Accurate diagnosis is essential in order to avoid unnecessary irradiation, and is made possible by a thorough training in dermatology; accurate therapy is equally essential and is made possible by a thorough training in radiology and biophysics. Ionizing radiations are not the dermatologist's only form of treatment or his most important one, but he is bound to use them when such use is imperative for the good of the patient.

The nuclear age is upon us. Atom splitting threatens to become as common in our time as rail splitting was in Lincoln's day. Recently, physicists and radiation health officers have been sounding alarms regarding the perils to mankind of a slowly increasing burden of radiation exposure. These warnings, chiefly of theoretical dangers to the evolutionary future of the human race, have been broadcast in the lay press. Unfortunately, the public is now beginning to mistrust radiation exposure to the point where many patients are refusing necessary diagnostic procedures and radiation treatments. Even in the medical journals, statements have been made[1] implying that the nonradiologist may be adding unjustifiably to man's mounting lifetime exposure by careless or unwarranted use of therapeutic or diagnostic radiation. The seeds of doubt and mistrust have thus been planted in the minds of many physicians.

It is time to separate facts from fancies among these fears. Just like the scalpel, radiation is a valuable medical tool, and it is also a highly dangerous one. In using it, are we in the medical profession really going toward our goal of helping humanity, or away from it? Today it behooves every medical user of ionizing radiation to conduct a thoughtful survey of his own use of the modality with this idea in mind.

The purpose of this paper is to review and evaluate the role of radiation therapy of the skin in this nuclear age, and, insofar as is possible, to answer the insistent question: "Is dermatological radiation therapy adding unnecessarily to man's increasing radiation burden?"

Dwindling Indications

Today, the dermatologist is using radiation therapy less and less frequently as newer, more effective methods are replacing it in the treatment of many skin diseases. Some diseases which were treated routinely by radiation as recently as three years ago are now more effectively treated by means of drugs or other modalities. In some of these ailments, roentgenotherapy is no longer indicated at all. In others, it is reserved for the most resistant cases.

Pyogenic Infections.—Antibiotics have entirely eliminated the necessity for roentgenotherapy in erysipelas, sycosis barbae, and lymphangitis. It is used less often than formerly for furuncles, carbuncles, and abscesses. Granuloma pyogenicum is now almost always treated by electrodesiccation and curettage.

Vulvar and Anal Pruritus.—Topical steroid therapy has brought dramatic relief to sufferers from pruritus vulvae or pruritus ani. I have found that simple cleansing with hexachlorophene (pHisoHex) is highly effective and many times the only form of treatment necessary after the vicious circle of itching and scratching has been interrupted by topical therapy with steroids.

Atopic Dermatitis and Localized Neurodermatitis.—Atopic dermatitis and localized neurodermatitis can usually be brought under control by means of topical steroid therapy and the new tranquilizing drugs, used in conjunction with other accepted forms of dermatological therapy.

Generalized Neurodermatitis and Autoeczematization.—Patients with generalized neurodermatitis and autoeczematization are now treated with steroids given orally or parenterally, precluding the use of total body irradiation.

Plantar Warts.—Many dermatologists have given up treating plantar warts with x-rays. They have found that a much greater percentage of cures can be obtained by using topical applications of monochloroacetic acid and salicylic acid plaster or by performing surgical curettage, two methods which are not at all dangerous in comparison with roentgenotherapy.

From the Division of Dermatology, Department of Medicine, Stanford University School of Medicine, San Francisco.

Read before the section on military dermatology at the 15th annual meeting of the American Academy of Dermatology and Syphilology, Chicago, Dec. 12, 1956.

Monilial Infections.—Nystatin has proved to be of much greater value than roentgen rays in the treatment of monilial infections of either glabrous skin or nails.

Granuloma Annulare.—The intradermal injection of hydrocortisone into lesions of granuloma annulare is fully as effective as irradiation and has virtually eliminated the latter in treatment.

Dermatitis Herpetiformis and Lichen Planus.—The sulfones for dermatitis herpetiformis and chloroquine or bismuth sodium triglycollamate (Bistrimate) for lichen planus have greatly reduced the need for x-ray treatment of these diseases. Cases of exfoliative dermatitis are seldom treated with total body irradiation. Steroids given orally or parenterally are more effective.

Granulomatous Diseases.—Certain granulomatous diseases are now treated with drugs instead of roentgen rays. Lupus vulgaris and tuberculosis verrucosa cutis respond to treatment with isoniazid and streptomycin; blastomycosis is treated with stilbamidine.

These examples show how the indications for irradiation in the therapy of skin diseases are dwindling. Furthermore, no new indications have been established during the past few years. The dermatologist is limiting his use of ionizing radiations to conditions which are resistant to other forms of treatment. This is a definite trend.

Softer Radiations

Another important trend in dermatological therapy is toward the use of softer radiations. Their use is aimed at confining irradiation to the disease process by limiting the depth dose. Although absolute and specific regulation of the depth dose of x-rays is impossible, several means exist whereby it can be controlled to a large extent.

Grenz Rays.—Over 75% of grenz radiation is absorbed in the first millimeter of tissue. Grenz rays are particularly suitable when ionizing radiations are to be used for diseases of the eyelid, scrotum, and female genitals where underlying structures are radiosensitive and must be protected. They can be used on the scalp, axillas, and eyebrows for treatment of superficial dermatoses without incurring danger of epilation, providing accepted dosage rules are followed. The use of grenz rays should be restricted to the most superficial disease processes. A knowledge of the depth of the pathological condition is essential.

The greatest danger with grenz rays is that the operator may be lulled into a false sense of security, thinking that because they are soft they are entirely safe and can be used almost indiscriminately on recurrent or chronic dermatoses. Grenz rays are ionizing radiations, just like x-rays or gamma rays. They can and do produce radiation sequelae when used in excessive doses. Accidental overdosage can easily occur if the machine has not been accurately calibrated or if the operator uses a combination-type machine producing either grenz rays or conventional superficial x-rays.

There are still other pitfalls. Small errors in target-skin distance or timing can cause appreciable alteration in dosage. Also, the dose will be increased by approximately 50% if an unnoticed surge on the power line boosts the voltage of a grenz machine from 10 to 12 volts.

Leading authorities [2] who have made accurate comparison consider that conventional superficial x-rays in doses of 85 r are more effective and give longer lasting benefit in the treatment of benign dermatoses than grenz rays in doses of 200 r.

Contact Roentgenotherapy.—Contact roentgenotherapy provides another means of limiting irradiation to the disease process. It is gaining in popularity among dermatologists for the treatment of small cutaneous carcinomas. The contact tube is designed to administer a cancericidal skin dose at very close range, incurring a minimal depth dose.

Intermediate Zone of Soft Radiations.—A third means of limiting the depth dose to the disease process concerns an almost unexplored field. It is what I call the "intermediate" zone of soft x-rays, with wavelengths between those of grenz rays and conventional superficial x-rays. The half-value layers range from 0.02 to 0.2 mm. of aluminum. Some of the newer superficial therapy machines include this range of radiation, furnished by beryllium window tubes. By using various filters, it is possible to obtain a wide range of radiation qualities. This enables the therapist to adjust the degree of penetration to the depth of the process to be treated. The physical attributes of these intermediate soft radiations are known, but the therapeutic indications and the required dosages have not yet been established. I predict that they will be established and that this range of radiations will be used more and more by dermatologists in the future.

Radioactive Isotopes in Dermatology

In the future, radioactive isotopes will no doubt be used instead of radium and radon wherever the former will give equal or better results with less danger to operator and patient. The purpose of their use in dermatological therapy will be not only to limit the depth dose but also to attain greater specificity in irradiation than is possible with other radiative means. Radium and radon are still widely used, but the fact that one is a powdered salt and the other a gas is disadvantageous, and an isotope can usually be found which will irradiate a given lesion more effectively and accurately than would be possible with radium or radon. Many operators have turned to such promising isotopes as cobalt-60 [3] and gold-198,[4] which in addition to their excellent therapeutic value, are metals and much safer to handle. Tantalum-182 [3b] has also been used successfully in gamma ray therapy of the skin.

Beta ray therapy in dermatology is coming back into its own, since pure beta-emitting substances are readily obtainable from the atomic pile. Phosphorus-32 [5] in flexible plastic sheeting has given good results in the treatment of widespread superficial lesions over awkward body contours. Elastoplast or cloth, impreg-nated with P^{32}, is also being used with good results[4] Strontium-90 plaques [3] are commercially available and can safely be used on the eyelid without danger to the lens. Ruthenium-106[7] can be electroplated onto molds of any shape for surface application. All of these are particularly suitable to dermatological use.

Evaluation

It is evident from the foregoing survey that the dermatologist of today is "roentgen conscious" and bent on using radiation sparingly, as he would any powerful medicine. We all realize that ionizing radiations are destructive rather than stimulating. However, they are still the most effective agents for the treatment of certain diseases, including some which are benign but nonetheless disabling.

As dermatologists, we are acutely aware of the physical and mental torture which can be caused by skin diseases. As doctors we are dedicated to the relief of suffering. Furthermore, we are taught, "do no harm." Are we, as dermatologists, doing unnecessary harm when we use ionizing radiations? That is the crux of the matter. To answer this question it is necessary to consider carefully how the dermatologist uses radiation therapy.

First, he uses localized radiation therapy. Localized body exposure has only the fractional significance of total body exposure. Even for workers who are exposed daily, the permissible dose to the extremities is five times as great as the permissible total body dose. Localized irradiation, even with large doses, produces no serious systemic effect, as can be confirmed by the fact that many thousands of people who have been so treated for skin cancer have remained healthy. In giving localized therapy, the untreated areas are covered with lead shields, or cones are used. In treating acne of the face, for example, the thyroid, scalp, eyes, and lips are shielded.

Braestrup,[8] consultant to the Atomic Energy Commission on radiation protection, recommends that "In order to reduce genetic effects, unnecessary irradiation of the gonads of patients who have not passed the reproductive age should be avoided. Whenever possible, the gonads should be shielded during irradiation of any part of the body. When shielding is not feasible, the dose to the gonads, and especially to the ovaries, may be reduced significantly by the use of x-rays of low penetration. This modification will permit irradiation of skin areas near the gonads."

Second, the dermatologist uses superficial radiations with half-value layers ranging from 0.02 to 3.5 mm. of aluminum. For treatment of benign dermatoses, the half-value layer is usually less than 1 mm. of aluminum. Radiations of this quality applied to the skin are insufficient to damage the liver, spleen, bone marrow, or reproductive organs. Filtration is kept to the minimum which will insure an adequate dose to the disease process.

Third, dermatological radiation doses are small, comparatively speaking, and are usually fractionated. Single doses are 75 to 85 r, seldom over 150 r, for benign diseases. They are given at intervals of one to two weeks. As soon as the disease begins to respond, treatments are either discontinued or spaced further apart, because it is known that the effect of ionization will continue for some time. In this way, the lowest possible dose is given. The dermatologist who gives his own x-ray treatments will give only the minimum amount of radiation, because he is familiar with the natural course of the disease he is treating and can observe its progress.

Superficial therapy of benign diseases has been criticized because of the possibility of serious sequelae. Witten and Baer[2] have published the results of a study which provides an excellent answer to such criticisms. One thousand patients who had been treated with roentgen rays for benign or malignant skin diseases were reexamined 5 to 23 years after treatment. No sequelae resulted from total doses of 1,000 r of superficial radiation. This amount of radiation was administered in fractional doses, of the qualities generally used by dermatologists in the United States for benign dermatoses.

"Cook book" therapy is to be condemned. One should not arbitrarily say that acne conglobata, for example, requires eight treatments of 75 r each, given a week apart. Why give 8, when in some cases 6 will be sufficient and in others 10 or more may be needed?

It is certainly true that the use of radiation in the treatment of benign diseases should be justified in every case. Where diseases of the skin are concerned, the dermatologist, because of his training and experience, is certainly the person most capable of deciding whether it is justified in the individual case. He is not primarily concerned with radiation but with the cure of skin diseases. Radiation is not his only form of treatment or his most important one. He is trained to use it when necessary to augment his specialized procedures and topical medication.

The last and most important point I wish to make is that no therapy is of any value unless a proper and accurate diagnosis is first made. In fact, misdirected therapy can cause irreparable harm to a patient. The dermatologist's ability to diagnose skin diseases correctly and his knowledge of the various therapeutic approaches enable him to save his patients from unnecessary irradiation.

All in all, I do not believe that many unnecessary roentgens are being added to man's increasing systemic radiation burden by the qualified dermatologist.

Comment

It is regrettable that neither the scientific nor lay press has sufficiently stressed the fact that the dangers warned against in the National Academy of Sciences report are not specific dangers to the health of the individual, but theoretical and statistical dangers to the future of the human race. In mentioning the so-called permissible dose, they have neglected to emphasize that diagnostic and therapeutic irradiation in whatever dosage is necessary must always be considered permissible.

There have been two full generations since ionizing radiations were discovered, but only recently have large numbers of the population received much medical irradiation. There has been no visible increase in the mutation rate, but such effects would not become evident for many generations. Studies based on total body irradiation of mice and fruit flies have shown that genetic mutations increase in number with an increase in radiation exposure. These findings are not capable of accurate extrapolation to human beings. Harmful mutant genes tend to be eliminated in the process of evolution.

We all have a small amount of radioactive potassium in our bodies, put there by Mother Nature, and we have been living with cosmic rays for thousands of years. Each of us receives about 15 r of total body irradiation from cosmic rays during his lifetime. The Atomic Energy Commission has estimated that each person has received an average of 0.1 r from all nuclear detonations up to the present time, including those of foreign nations. This is less than 1/100 of the average total lifetime dose from cosmic rays. People living at high altitudes get more than twice as much cosmic radiation as those living at sea level, yet such people as the Swiss Alpine mountaineers are very hardy. Also, there are areas in the world where large deposits of uranium ore make the ground highly radioactive, yet the natives of these areas have subsisted and perpetuated their kind for countless generations.

The evolutionary power of cellular recovery develops irrespective of the type of noxious agent causing damage." It is logical to assume that the human body has a greater power of adaptation to environment than that of the mouse or the fruit fly.

True, it gives us an uneasy feeling when we realize that nothing is known about the long-range effects of radiation on the race of man, but perhaps there is no reason to assume that all of these effects will be bad ones and that there are no hidden remedial factors.

Experiments have shown that the life span of mice and rats is shortened by total body exposure to radiation above a certain limit of tolerance. This is considered by many to be cause for alarm in relationship to human beings. Yet, the span of human life has increased by 20 years since the discovery of ionizing radiations. A share of this increase is certainly due to the accurate and prompt diagnoses made possible by the use of diagnostic x-rays. The therapeutic use of x-rays has lengthened the lives of many patients with fatal diseases and has, in fact, cured many others, enabling them to live out their normal life expectancies. Are we to go backward in history because of a fear of radiation?

Within the medical profession, the fear of radiation therapy has been heightened by the fact that one medical group has pointed an accusing finger at other groups for misusing it. Actually, a few in all these groups have misused this modality. The criterion for using ionizing radiation should be that the user is trained in and understands radiation physics and biophysics and that he knows what he is treating, rather than that he should be a member of any particular coterie. No candidate can be certified by the American Board of Dermatology unless he is adequately trained in radiation and biophysics pertaining to superficial therapy and knows the indications and contraindications of irradiation of skin diseases.

Conclusions

This is a time for caution, but not for panic or fear of the unknown. The careless or casual use of radiation is to be condemned in any age, but the hazards of even this nuclear age are not sufficient to warrant the withholding of wisely administered radiation therapy from those who really need it.

When we use drugs, we have to consider the therapeutic index, that is, the amount of good the drug will do in comparison with the amount of harm it may possibly do. Radiation, too, has a therapeutic index. There is no safe dose, except for the patient who would be in much worse condition without it!

Those who sound warnings in the newspapers are doing a great disservice in alarming the public. Groups of physicians who cast aspersions on the use of radiation by other groups are doing a disservice to the medical profession. I am sure it will not help the cause of humanity to have the minds of the public or the physicians poisoned against radiation therapy. We must differentiate between mice and men, between total body irradiation of well people and medical irradiation of sick people.

We are doctors, bound by our Hippocratic oath to give our patients the best possible form of treatment for their ailments. We are in honor bound to use radiation therapy where it is imperative for the good of the patient.

1120 Montgomery Dr.

DIFFERENTIAL DIAGNOSIS OF CONGENITAL HEART DISEASE IN INFANCY

Bernice G. Wedum, M.D., Washington, D. C.

The relative value of the various data obtained from physical examination, history, electrocardiography, fluoroscopy, and roentgenography in the diagnosis of congential heart disease can be determined only from a series of patients whose thoracic viscera have been actually seen during subsequent surgery or at autopsy. Study of 279 autopsies of children has led to the formulation of 11 questions that should be answered in making a diagnosis. Painstaking analysis of all available data is important because an accurate diagnosis is possible in many cases. Surgery sometimes offers the only chance for survival, and for some congenital malformations surgery is not only palliative but curative.

It may be unequivocally stated that no discussion of the differential diagnosis of congenital heart disease should be based on other than autopsy evidence,[1] evidence obtained from surgery, or, in a few instances, from catheterization data which are as conclusive as autopsy evidence. The following discussion is based chiefly on a study of 279 autopsies performed at Children's Hospital in Washington, D. C., during the years 1935-1956. Observations at surgery considered equivalent to autopsy evidence are division of a patent ductus arteriosus, valvulotomy for infundibular or valvular pulmonary stenosis, excision of a coarctation, and closure of a septal defect. Catheterization data considered conclusive are passage of a catheter through a ductus or aortic septal defect, the catheter appearing below the diaphragm; and significantly high right-ventricular and low pulmonary-artery pressure establishing the presence of pulmonary or infundibular stenosis. In no instance is an associated lesion excluded. There is no quick and easy short cut to the diagnosis of congenital malformations. The evidence must be carefully gathered and painstakingly evaluated in every case.

History and Physical Examination

The history of the presence or absence of cardiac enlargement at birth is of importance, since relatively few lesions cause a strain on the heart sufficient to cause enlargement in fetal life. Congestive failure in infants is initially characterized by rapid respirations and usually, as it progresses, by liver enlargement; occasionally rales at the lung bases are prominent. The character and time of onset of congestive failure are of importance as indications of the severity and nature of the lesion and whether a very marked strain is thrown on either the right or the left ventricle. Of value is a positive history that the child either very definitely never has been cyanotic or very definitely has been cyanotic. There is a group about which one cannot be entirely certain as far as history is concerned. Observation of different degrees of cyanosis of the hands and feet in infants is not reliable, although a difference in the degree of cyanosis of the right and left hands, while rare, is significant. The character of the cry and the history either of anoxemic attacks or of any type of spells or feeding difficulties are of importance.

When approaching an infant for a physical examination one notes initially the degree of cyanosis at rest, observing the baby quietly without disturbing him, and then listens with the diaphragm of a Riger Bowles stethoscope to the character of the second sound, noting the presence or absence of a murmur, its character, and the pulse and respiratory rate. The rest of the information one wishes, e. g., the character of the pulses; the presence of edema, rales, liver enlargement and pulsation, and jugular distention and pulsation; presence of a thrill; and distribution of cyanosis, can be obtained accurately whether or not the baby is disturbed.

The blood pressure should always be obtained in both the arms and legs, using the flush technique with two cuffs if auscultation is not satisfactory. A cuff folded so that it may fit snugly around one-half to two-thirds of the upper arm is put in position. Another cuff is placed around the wrist and hand and pumped up to 300 mm. Then the cuff around the arm is quickly inflated above the expected systolic pressure and the hand cuff is released. The wrist and hand should be waxy white. The arm cuff is slowly and carefully deflated while the observer watches carefully for the appearance of the first flick of returning color. Values average about 10 points below those obtained by auscultation. In taking pressures in the leg it is of crucial importance to fold the cuff so that the same ratio is maintained between the cuff and upper leg as in the upper arm.

Questions That Aid in Diagnosis

Consistently accurate diagnoses can be made from good x-ray films alone, but a careful fluoroscopic examination in experienced hands is of importance.

Pediatric Cardiologist, Yater Clinic, Washington, D. C., and Consultant Cardiac Pathology, Children's Hospital of Philadelphia.

If, with an accurate history, careful physical examination, good x-ray films, fluoroscopic examination, and electrocardiograms, the data are carefully analyzed, and certain questions asked, one can make an accurate diagnosis in a surprisingly high percentage of cases. The questions discussed below are among those that aid in diagnosis.

1. Which chambers are enlarged? Are both ventricles and both auricles present? Is there a single ventricle or inversion of the cardiac chambers?

A study of the x-ray films and electrocardiograms can usually eliminate marked left-ventricular enlargement, as in subaortic stenosis, or marked right-ventricular enlargement, as in aortic atresia, as diagnoses. The voltage of the electrocardiogram in the precordial leads is the most reliable indication of chamber enlargement in infancy, if allowance is made for the normal right-ventricular preponderance during this period. Although the heart may weigh as much as twice the normal at autopsy, x-ray films may show little evidence of enlargement. Measurements of the intrinsicoid deflection are not ordinarily of value in infants' hearts because the ventricular wall must increase roughly 4 mm. in thickness to produce an increase of 0.01 second in the width of the intrinsicoid deflection, and hypertrophy of this degree seldom occurs in infancy.

Enlargement of the right ventricle is difficult to diagnose by x-ray examination except when it is marked, as in a truncus arteriosus. The anterior contour on fluoroscopy projects forward and may infringe on the sternum in the left anterior-oblique position; sometimes this is better seen in the right anterior-oblique position. Considerable enlargement of the right ventricle may be present without producing striking changes on fluoroscopy or x-ray examination.

A large peaked P_2 in the electrocardiogram is pathognomonic of an enlarged right auricle, although the right auricle may be enlarged without this finding. The high voltage of the P wave appears to bear a rough relation to the pressure in the right auricle. In a transposition of the great vessels, where the right auricle may be anatomically as large as the right auricle of an isolated pulmonary valvular stenosis, the voltage of the P wave is not increased. It is increased when pulmonary stenosis is present. Broad P waves in lead 2 suggest left-auricular enlargement, although posterior deviation of the esophagus seen on x-rays made after a barium swallow is the most reliable indication of enlargement of this chamber.

The diagnosis of a single ventricle cannot be made with certainty from the electrocardiogram, in spite of the absence of the ventricular septum. The precordial leads usually show "right-ventricular preponderance," although "left-ventricular preponderance" may be present. With evidence of combined ventricular hypertrophy, diagnosis of a single ventricle may be excluded with a fair degree of certainty. If the cardiac contour is somewhat bizarre, with more of the ventricular portion on the right than usual, a single ventricle may be suspected, although this indication of arrested development before the bulboventricular loop swings to the left may occur in any primitive heart. If the heart appears enlarged in the anteroposterior position and flattened in the left anterior-oblique position, a single ventricle with complete transposition may be suspected. The basic lesion in this malformation is usually inversion of the bulboventricular loop, and the resulting flattening of the heart is reflected in the oblique position. The anatomy of the various forms of single ventricle without transposition may be readily correlated with the stage of embryologic development at which arrest has occurred, and some malrotation of the vessels is the rule, but the anatomy of a single ventricle with complete transposition is very different and is usually the result of inversion.

True inversion of the auricles is extremely rare but when present may be readily diagnosed by the character of the P waves in lead 1 and lead aVR, which is that of a dextrocardia. In a dextrocardia an upright P wave in lead 1 also means inversion of the auricles. Inversion of the ventricles is even rarer and is present in a true corrected transposition. Even at the autopsy table it is sometimes difficult in the more complicated malformations to ascertain whether ventricular inversion is present.

2. *Which great vessels are enlarged? Are both present, normal, and in normal positions? Their branches?*

Moderate degrees of enlargement of the pulmonary artery are best observed in the right anterior-oblique position. When a true truncus arteriosus is present there is a distinct widening of the great-vessel shadow in the anteroposterior position which is not present when partitioning of the truncus has occurred with subsequent atresia of the pulmonary artery. When the pulmonary artery is absent the very clear pure second sound is quite characteristic. The absence of a murmur in an infant always raises the question of complete pulmonary atresia. It should be remembered that, even if the pulmonary artery is absent, right and left pulmonary arteries are, more often than not, present for operative purposes. The presence of an atypical continuous murmur should always raise the question of complete absence of the pulmonary arteries, since the blood supply to the lungs in this case may be by way of bronchial arteries from a true truncus arteriosus, and in this instance right and left pulmonary arteries are not present for operative purposes. When the blood supply to the lungs is via a patent ductus arteriosus in pulmonary atresia a continuous murmur is not present, and, as has been said, usually no murmur is present.

A narrowing of the great-vessel shadow may indicate a hypoplastic aorta, which is a rather constant feature of an atrioventricularis communis. This finding is also present in complete transposition of the great vessels with a widening of the shadow in the left anterior-oblique position. Often the great vessels will not be completely transposed, and in these instances the width of the great-vessel shadow is of no help. When the pulmonary artery overrides, it is greatly enlarged. An esophagram should reveal a vascular ring, anomalous right subclavian artery, or right aortic arch. Preductal coarctation is accompanied by slight but definite difference in blood pressure (more than 15 points) between the arms and legs with the flush technique, and usually right-ventricular enlargement in early infancy and marked right-sided failure. Cyanosis of the feet may or may not be present and is not usually a helpful point in differential diagnosis.

The clinical story in an infant with anomalous origin of the left coronary artery from the pulmonary artery is so characteristic that the experienced pediatric cardiologist will suspect the diagnosis from the history. If one has once seen such an infant in the course of the attacks of anginal pain which these children experience, one will not fail to recognize their nature. The electrocardiogram shows evidence of marked left-ventricular enlargement such as can occur in extreme subaortic stenosis or endocardial fibroelastosis, which cannot be differentiated from anomalous origin of the left coronary artery from the pulmonary artery from the electocardiogram.

When the baby has any signs of cerebral anoxia, such as "spells" or slow respirations where rapid ones would be expected, the aorta almost certainly arises from the right ventricle or is in some manner receiving a large amount of venous blood. Similarly, if the coronary arteries are receiving blood which is almost entirely venous, the voltage on the electrocardiogram may be low, indicating myocardial anoxia. Although this may not always be the case, when such a finding is present it is most helpful. One or both of these findings should always bring to mind the possibility of extreme dextroposition of the aorta with pulmonary stenosis. This is an important point because when extreme dextroposition is present an auricular septal defect should always be created in addition to an anastomosis.

3. *Is the systemic venous return normal?*

This question cannot be answered in infants without angiocardiography but should always be borne in mind when considering cyanosis not readily explained on other grounds. It is very often abnormal in isolated dextrocardia and levocardia with situs inversus and in a congenital malformation associated with congenital absence of the spleen. Distention of the superior vena cava without evidence of a shunt in the lung fields may indicate a rare anomaly of the abdominal venous return.

4. *Is the pulmonary venous return normal?*

When all pulmonary veins drain into the right auricle the lung fields are obviously congested, although in the newborn child the congestion may not be as striking as it is when the child survives for a few months. There is great right-auricular enlargement. This malformation can be readily diagnosed during life, although the findings closely resemble those in aortic atresia and preductal coarctation. Infants with aortic atresia seldom survive beyond the first month of life.

Cyanosis is not marked in these cases and is of the type that goes with a reduced cardiac output, which differs so markedly from that which accompanies a venous arterial shunt. Partial anomalies of the pulmonary venous return have no sharply distinguishing features. Rare anomalies such as complete atresia of the pulmonary veins with the pulmonary venous return by way of the bronchial veins are occasionally encountered. It should also be remembered that the anomalous pulmonary venous connection may be with the inferior vena cava.

5. *Is an arteriovenous shunt present?*

In infants this can be most readily determined by a study of the vascularity of the lung fields. It should be remembered that the lung fields of newborn children are deceptively clear. Such a shunt may occur by way of a pulmonary vein, auricular septal defect, patent foramen primum, atrioventricularis communis, ventricular septal defect (including the rare form where the jet is into the right auricle), aortic septal defect, overriding pulmonary artery, truncus arteriosus, patent ductus arteriosus, ruptured aneurysm of the sinus of Valsalva, arteriovenous aneurysm of the lung or coronary sinus, and coronary artery. The second sound in the second left intercostal space is almost invariably somewhat accentuated if a shunt is present. It should be remembered that the communications mentioned above may be present, although no shunt, or a venous-arterial shunt, may be present. If the second sound is diminished or absent, an arteriovenous shunt is most unlikely.

6. *Is a venous-arterial shunt present?*

In small infants the presence of mild degrees of cyanosis is not very easy to detect, and infants who at postmortem examination reveal lesions which must have produced a venous-arterial shunt still will have shown only little or questionable cyanosis clinically. Infants with a diminished cardiac output may show an entirely different type of cyanosis due to peripheral stasis. When definite unquestionable cyanosis is present, it usually means that a venous-arterial shunt of considerable magnitude is present, but, if it is only questionable or not detected, a venous-arterial shunt may still be present. A lesion theoretically causing differential cyanosis in the hands and feet may not in fact cause it.

7. *Is congestive failure present?*

The diagnosis of congestive failure in infancy when it is early and minimal is not easy; it can be readily confused with pneumonia. The earliest sign of failure in infancy is an increase in the respiratory rate. The white blood cell count is of little help, surgery. If no patency is found and no remedial surgery is performed, the child has, in addition to his cardiac lesion, the stress and strain on the heart that is produced by a thoracotomy.[4a]

Atrioventricularis Communis.—The clinical electrocardiographic and x-ray findings in an atrioventricularis communis are usually, although not invariably, characteristic, with left-axis deviation and right-ventricular preponderance on the electrocardiogram. It is, however, possible to confuse this lesion with certain forms of single ventricle with complete transposition. It should be stated in passing that a true patent foramen primum is a rather rare lesion, and most cases of the "patent foramen primum type" described in recent reports are in actuality cases of atrioventricularis communis. An atrioventricularis communis should be closed with the use of a pump-oxygenator, using a prosthesis, with no attempt to close the lower posterior margin except for a few fine anchoring sutures to the surface of the center of the posterior endocardial cushion. Defects under this structure, which are usually small, should not be repaired, since this cannot be done without danger of interfering with the conduction system. Possibly a collar-button-shaped piece of nonabsorbable polyvinyl (Ivalon) sponge could be pushed through such a defect and anchored a safe distance from the crest of the ventricular septum in the right ventricle. An obvious cleft in the anterior cusp, formed by a failure of the left tubercle of the anterior endocardial cushion to fuse with the parietal half of the primordium of the anterior cusp of the mitral valve, should be repaired, but no attempt should be made to reconstruct the anterior and posterior endocardial cushions into a normal posterior mitral cusp and septal tricuspid cusp.

Ventricular Septal Defect.—The diagnosis of a ventricular septal defect in small infants is most difficult and is essentially an exclusion diagnosis. If an acyanotic infant or one with only transient episodes of cyanosis in congestive failure does not prove to have a patent ductus arteriosus, the characteristic findings of an atrioventricularis communis, a contour suggesting a single ventricle with transposition, the pressure differences of a preductal coarctation, or the contour and characteristic second sound of a truncus arteriosus from which the pulmonary arteries arise, he probably has a rather large ventricular septal defect which communicates between the left ventricle and the inflow tract of the right ventricle in proximity to the septal cusp of the tricuspid valve or, more rarely, into the infundibulum of the pulmonary artery. There is more likely to be overriding of the aorta in infancy (Eisenmenger complex). A large auricular septal defect—even a single auricle as an isolated lesion—does not usually produce congestive failure in early infancy. Children with isolated ventricular septal defects who go into failure in infancy will usually survive with vigorous antibiotic therapy and treatment of their failure. Rarely such children will not respond, and these infants may benefit from a "pulmonary tuck" operation[5] as a stopgap procedure with the hope that they will survive to an age when open cardiac surgery is less hazardous. The decision must be carefully weighed in each individual case. A ventricular septal defect is often accompanied by a small auricular septal defect.

Endocardial Fibroelastosis and Anomalous Origin of Left Coronary Artery.—Endocardial fibroelastosis and anomalous origin of the left coronary artery from the pulmonary artery are distinguished by marked left-ventricular enlargement, both on x-ray and electrocardiogram, in a child without cyanosis or evidence of a shunt or aortic stenosis. (However, right ventricular preponderance may accompany endocardial fibroelastosis in the presence of an associated anomaly of the mitral valve.) A secondary type of marked endocardial fibroelastosis, which is quite distinct from the primary type, develops in all cases of anomalous origin of the left coronary artery from the pulmonary artery. For this reason, a simple transposition of the segment of the pulmonary artery from which the left coronary artery arises to the aorta, even if technically possible as an open procedure, would not be physiologically sound. These two lesions should both be treated by one of the procedures for vascularization of the left ventricle.

Aortic Stenosis.—Children with congenital aortic or subaortic stenosis, lesions which are rare, should have open remedial surgery without too much delay, if they are having fainting spells. These children have a tendency to die suddenly, and marked myocardial fibrosis due to coronary insufficiency is found in those who survive for any period.

Comment

Far too many infants are being allowed to die of congenital malformations of the heart for which not only palliative but curative surgical procedures are available. Funds are available to provide financial assistance for such children and although the surgical mortality is admittedly high these infants should have their chance for survival. They remain the greatest challenge in the field of cardiovascular surgery.

An infant with a congenital malformation amenable to surgery should only be operated on at a center with a record of successful achievement in older children with less complicated malformations and facilities for handling small infants. It is an experienced, smoothly organized team which is most needed for success, regardless of the abilities of individual members. Given an experienced team, it is the abilities and experience of the surgeon which are paramount. It has been my observation that it is the centers and surgeons with the most experience who are most keenly aware of their own limitations and most willing to refer complicated cases to those in whose hands the patient's chances for survival are the greatest.

Summary

The differential diagnosis of congenital malformations of the heart in infancy requires painstaking analysis of all available data. An accurate diagnosis can be made in a high percentage of the cases in which the lesions are amenable to surgery. Infants with congenital malformations should be operated on only in centers where experienced personnel are available.

TWIXT THE CUP AND THE LIP

Harry F. Dowling, M.D., Chicago

The development of a drug is an intricate process, involving researchers, manufacturers, clinical investigators, and many others. All of the information obtained about the drug must be brought to the practicing physician, who is the one to prescribe or administer the drug, and it is important that this information be timely and accurate. In the evaluation of new drugs, the practicing physician should do three things. First, he should learn the mechanism by which the drug works, rather than the results somebody says it will produce. By learning the generic name, the physician can understand much about the drug. Second, when asked by a patient to prescribe a drug that is not indicated, the good physician explains rather than prescribes. Last, doctors should read pharmaceutical advertisements critically, and not be hesitant to write to editors of journals as well as drug manufacturers when they question the truth. Only in these ways can the medical profession advise and assist such a dedicated organization as the Food and Drug Administration to properly judge the merits of a drug.

Drugs are discovered, manufactured, and tested by scientific methods. On the other hand they are produced and marketed through a blend of personal and social motives; they are prescribed by doctors with varying knowledges and skills, and they are taken by patients who have different degrees of information, interest, and precision. Drugs are brewed in the cup of science; they are drunk through a patient's lips, and "there's many a slip twixt the cup and the lip."

Scientific attention is usually turned toward the discovery of drugs; in the present paper I shall consider the path from their development to their use. As an example, let us take chlortetracycline, one of the first antibiotics to be produced by a pharmaceutical company. After screening hundreds of specimens of soil, Duggar isolated Streptomyces aureofaciens, in the fall of 1945. Its in vitro antibacterial activity was demonstrated later in the same year.

Preparation of crude concentrates that protected animals against bacterial infections required an entire year, and further purification and initiation of large-scale production required nearly two years more. It was not until September, 1948, that clinical tests were considered adequate for submission of the data to the Food and Drug Administration. Approval by this agency was granted in October, 1948, and chlortetracycline was finally marketed on Dec. 1, 1948.[1]

From the Research and Educational Hospitals and the Department of Medicine, University of Illinois.

Chairman's address, read before the Section on Experimental Medicine and Therapeutics at the 106th Annual Meeting of the American Medical Association, New York, June 4, 1957.

The path of a drug from cup to lip, which took over three years in the case of chlortetracycline, is shown in Figure 1. Basic research by medical schools, pharmaceutical companies, and others leads to the discovery of a new drug. It is produced in a form suitable for administration by the pharmaceutical manufacturer. Its efficacy must then be tested in vitro, and its efficacy and toxicity, in lower animals. If these tests are satisfactory, the drug is tried in patients by investigators outside of the pharmaceutical industry. The accumulated information is then submitted to the Food and Drug Administration for approval or to the National Institutes of Health in the case of biological products. When approval is forthcoming the drug can be packaged, advertised to the profession, and sold. At the same time, investigators who have tried the drug in patients are informing the medical profession when and how this drug should be used. All of these paths lead a single goal: administration to patients. This benefits the patient through the prevention, amelioration, or cure of disease and brings profits to the pharmaceutical industry and related groups. These twin benefits act as sources of energy to start the process over again.

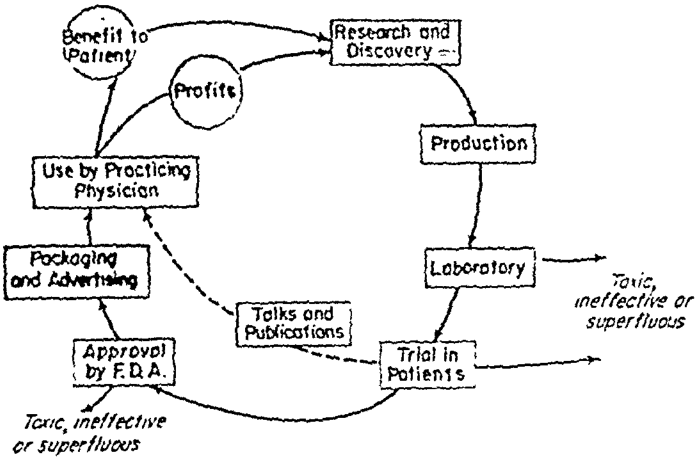

Fig. 1. Diagonal lines refer to the pharmaceutical industry; horizontal lines, to the investigators in medical schools and hospitals, and stippled areas to other groups (government agencies, the practicing physician, and the patient).

This system is an outstanding example of man's genius for organization. It has been developed by idealistic motivation, along with down-to-earth planning; it balances the interests of scientist, investor, producer, physician, and patient. And it has filled the cup to overflowing. The number of effective drugs is beyond the highest hopes of a century ago and is increasing all the time. In the thirty-year period from 1905 to 1935 new drugs were introduced into the United States "Pharmacopeia" at a rate that averaged six per year, while in the succeeding twenty years the average yearly rate was thirty-seven.[2]

Yet the system, like all systems, can be perverted. The process of fundamental research, followed by the development of worth-while new products and the successive stages necessary to bring them to the patient, is a long one. The desire to help the patient and the desire for profits provide sufficient energy to power the process; but some have discovered that if this energy is applied at a later stage, the path from profit back to profit again can be speeded up. This is shown in Figure 2. Energy, instead of being directed toward research and the discovery of new drugs, is frittered away on dozens of unimportant modifications designed to compete with drugs that are already available. One example of this is the marketing of mixtures of antibiotics. As of November, 1956, there were on the market twenty-nine preparations containing two antibiotics, twenty containing three, eight containing four, and four preparations that contained five antibiotics apiece.[3] I have shown elsewhere [4] that there is no good reason for the use of any of these sixty-one mixtures.

If this trend continues, we shall soon reach the chaos that exists in Germany. According to a recent article in The Lancet,[5] there are about 6000 proprietary preparations marketed in Western Germany, made by 565 different firms. Most of these preparations contain several or many substances; five or six is the rule, and more than ten is not at all rare. One firm has put twenty-two different substances into one tablet. It has become unfashionable to use one drug by itself. When the author of the article asked for ephedrine tablets in a big hospital, he was told that these were no longer stocked.

This side-tracking of energy within the system has further effects. When the drugs that are produced so prodigally are tested in the laboratory, only those are eliminated that are obviously toxic. Drugs that are superfluous because they duplicate the action of others that are already available and drugs that are of dubious effectiveness are continued in the process and eventually reach the market (Fig. 2). For instance, thirty-three different antihistiminic drugs are being sold at present,[6] all having practically identical actions but different names and dosages. Similar excesses can be found among other groups of drugs, especially the vitamins, the antispasmodics, and the tranquilizing drugs.

At the next step in the process pressure is applied upon investigators to report that all the drugs recently produced are beneficial to patients, that they are better than existing drugs, and that they have fewer side-effects. Since this tremendous multiplication of new drugs exhausts the existing facilities for clinical investigation, inexperienced investigators are cajoled into assessing drugs in patients. Some learn the proper methods and acquire a critical sense during the experience; most do not but unwittingly call a spade a diamond—to the confusion of the Food and Drug Administration, the exasperation of the experienced and honest investigators, the quick profit of that particular manufacturer, and the loss of prestige of the medical profession and of the pharmaceutical industry as a whole.

Increased pressure is applied in turn upon the Food and Drug Administration. No words can speak too highly of the services rendered to physicians and patient alike by this dedicated body of public servants. Quietly and unobtrusively, patiently and honestly, they attempt to judge the merits of a drug solely on the evidence presented to them. Their problems, however, are similar to those of every regulatory agency of the government: they hear one side of the story loudly and incessantly; they hear the other side only sporadically and feebly. It is the drug manufacturer's business to present his viewpoint; it is to his interest to present it attractively and forcibly. The consumers, on the other hand, have no paid advocates. Their viewpoint is presented by persons who must spare time from everything else to do it and who are not usually well acquainted with these channels of communication. This is all the more reason why, in the field of the regulation of drugs, physicians and organizations of physicians, such as the American Medical Association, should make it their business to advise the Food and Drug Administration.

The excess pressure is applied next to advertising. The description of the drug on the label and the circular accompanying the package must be accurate and well documented and must be approved by the Food and Drug Administration. Advertising pertaining to a drug, on the other hand, is under the jurisdiction of the Federal Trade Commission, who can stop a company from making a particular statement only if the statement constitutes an unfair or deceptive act. This opens the way for abuses.

Within recent years the drug industry has discovered that the techniques that had been used so successfully in the advertising of soaps and tooth pastes and of cigarettes, automobiles, and whiskey could be used as successfully to advertise drugs to doctors. Advertising to doctors has become flamboyant, as shown by two-page gaily colored spreads in nearly every medical journal. Advertising has become incessant; nearly identical advertisements for a new drug appear in each day's mail for weeks on end. Advertising is without question confusing. The multiplicity of trade names makes it difficult to remember the actions and uses of any. Richardson Evans, writing in the English *National Review* in 1890, said: "Suppose a dozen people are in a small room. Two begin to talk to each other at the top of their voices. The others must either give up conversation or shout also. The result is that no one hears as well as before and that comfort is at an end. So it is with advertising. . . ."[7] Advertising to doctors has now reached this peak, and we are deafened by the din.

This leads us to the next step in the process: the use of drugs by the practicing physician. The doctor's sources of information include textbooks, journals, and speeches, written or delivered by those who have studied the drugs in laboratories and in patients. Most practicing physicians do not see a sufficient number of patients with any one disease to make a critical trial of a new drug themselves. When the drug becomes available the most they can do is to acquire skill in its use. If this information is "beamed" clear and true to the doctor, he is willing to listen to the "commercials" and patronize those who have, through their investments and their foresight, brought the drugs to him. But today the "commercials" are so loud, incessant, and brash that they jam the channels of communication. The bewildered physician prescribes by suggestion and not from information.

At this point the reader will say: "Well, even if this makes the physician a shifting weathervane and the patient an unwitting guinea pig, the writer must be an ingenuous idealist to expect the pharmaceutical manufacturers to change their methods so long as they are putting money in their pockets." This last phrase is the key to the answer. You will recall that the twin sources of energy for the system are profits and benefit to the patient. It is already evident to most doctors, and it will soon become evident to the public, that energy has been diverted from the pathway that leads to the greatest benefit to patients. With the inevitable disillusionment that comes with the failure of each useless modification to make any advance, the pharmaceutical industry will lose its prestige and with this will lose its financial backing. It will fall, and the medical profession will be dragged down with it. Since such a catastrophe would involve doctor, industry, and patient alike, we may well look to see what each can do about it.

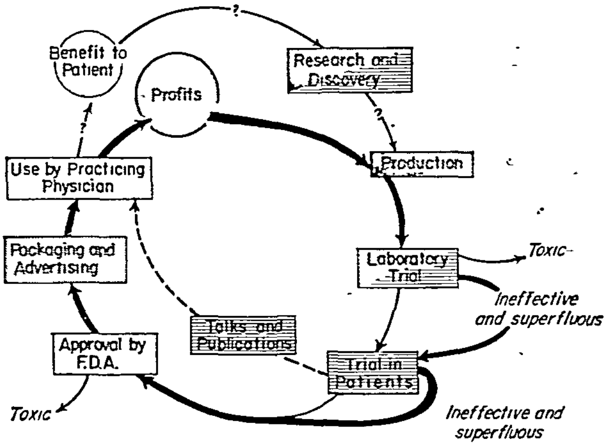

Fig. 2.—See figure 1 for key.

To physicians I would say first: Keep informed. Learn the mechanisms by which drugs work, rather than the results somebody says they produce. Look for and remember the generic name, for this tells something about the drug, while the trade name tells nothing. Avoid substituting drugs for diagnoses.

Furthermore, since advertisements for new drugs appear so quickly, some mechanism must be set up to bring authoritative information rapidly from investigator to practicing physician. The challenge is thrown to medical societies, medical schools, and specialty groups: keep the profession informed!

My second suggestion to physicians is, inform the public. As Vannevar Bush has said[8]: ". . . public opinion is not formed by the radio and the press or even by those who control these media. It is formed by that minute fraction of the population which thinks and speaks, by that small but powerful minority, disagreeing on every issue, arguing and ridiculing, which looks beyond the diversion of the moment and influences because it labors to understand." With regard to drugs we are that "small but powerful minority," and we must use every means to make our opinion known. When a doctor prescribes a drug for no reason except that the patients wants that drug, the doctor is allowing the lay press to take over the job of health educator to his patients. The good physician explains instead of prescribing.

My third suggestion to doctors is to reject misleading information and repudiate those who purvey it. Doctors should read advertisements critically. They should write to editors of journals and to drug manufacturers when they question the truth of an advertisement. They should not listen again to someone who has misled them once. They should prescribe as far as possible only those drugs made by companies with high standards of advertising and read only the journals that accept that kind of advertising.

In the past the Council on Pharmacy and Chemistry of the American Medical Association (now the Council on Drugs) has led the fight against false advertising by quacks and vendors of patent medicines. The battle front of today has shifted, and false advertising to the public is no longer the major issue. For the future the Council needs to align its forces against false advertising to the doctor.

To pharmaceutical manufacturers, I would make three suggestions: (1) that they emphasize basic research and the discovery of new drugs and avoid minor variations of existing drugs; (2) that they weigh the proposals of their sales departments in the light of advice from their scientific staffs and from competent impartial clinical investigators, and (3) that they revise their advertising methods. Advertising should not be premature; advertisements for a new drug should not appear before a single clinical article is published in a reputable medical journal. Advertisements should be in keeping with the dignity of the industry from which they come and the good sense of the profession to which they go. The time is already past due for reputable manufacturers to establish a code of ethics for advertising and abide by it. When this has been done the words "ethical manufacturer" will mean a manufacturer who works for the good of the public rather than meaning, as at present, one who advertises only to the medical profession, no matter how he advertises.

The regulatory agencies of the government function as impartial judges for the benefit of the consumer. Laws always lag behind actuality, and budgets are always deficient; but in spite of these limitations the regulatory agencies deserve great credit for keeping the present system from getting out of hand altogether. How can they do the job better? Certainly they should insist upon honest and thorough investigations by clinical investigators. They should inquire how the cases were obtained for trial; were they selected out of a larger number of cases and, if so, by what criteria? Funds should be available to them for financing tests of drugs when the evidence submitted is equivocal or unconvincing. They should also be able to employ consultants to advise them in difficult cases. These agencies need the strong backing of the medical profession; the patient's welfare must be kept continually before them so as to counteract the obvious pressures from the pharmaceutical industry.

Many people believe that the laws should be amended so that the Food and Drug Administration can pass on the efficacy of a drug. At present, except in the case of the drugs that are certified, which include insulin and certain antibiotics, the Food and Drug Administration cannot prohibit the sale of an ineffective drug; its only recourse is to seize the drug as misbranded if a therapeutic effect is claimed in the circular that accompanies the package. This seems a roundabout way to protect the public.

Furthermore, the present laws leave all advertising, except that which accompanies the package, to a separate agency, the Federal Trade Commission. In spite of the excellent cooperation that exists between the two agencies, this is a cumbersome method which has not succeeded in giving adequate protection to the patient. Many people believe that the law could be enforced more efficiently and more completely if advertising as well as labeling were regulated by the Food and Drug Administration.

My suggestions can be summarized in two words: information and regulation; prompt and exact information for the practicing physician from the investigator, the professional societies, the medical journals and the specialty groups; willingness on the part of capable investigators, teachers, and other leaders in medicine to spend time in spreading the truth about drugs; probity and sanity on the part of the manufacturers in keeping advertising factual rather than suggestive, direct rather than irrelevant, truthful rather than misleading; recognition on the part of the practicing physician that his is the final responsibility for the use of a drug and that he cannot give this decision over to anyone else. Regulation there must be for those who will not work from higher motives: regulation by industry to the extent that it can be done; regulation by organizations of physicians where they can help, and regulation by government where the others fail to do the work. Let those who object to the third alternative strengthen the first two.

These things should be done; these things can be done; shall we here agree that these things will be done? In the words of George Washington, "Let us raise a standard to which the wise and just can repair."

UNIFORMED SERVICES DEPENDENTS' MEDICAL CARE PROGRAM

Major Gen. Paul I. Robinson (MC), U. S. Army

A program to provide improved, standard medical care for dependents of members of the Army, Navy, Marine Corps, Air Force, Coast Guard, and certain other uniformed government services was established by law Dec. 7, 1956. Six months of operation yielded data from 21,363 cases indicating the trend of the program. Maternity cases comprised 47% of the total. Twenty per cent of the participants in the program were males, and the majority of these were children. Physicians' fee schedules have been developed with the help of teams comprised of a physician, a certified contracting officer, a lawyer, and an auditor. It has been difficult to specify how much service should be included for a given fee. Other problems include the provision of emergency care for acute emotional disorders. The program appears, nevertheless, to be a workable one and has enlisted the combined efforts of many national and state organizations.

The Dependents' Medical Care Program is designed to provide improved and uniform medical care for dependents of members of the uniformed services and thereby enhance the morale of service personnel. The program continues the provision for medical care in uniform service facilities for authorized dependents of both active duty and retired personnel; parents or parents-in-law (if dependent and provided the parent or parent-in-law actually resides in a household provided or maintained by the member); and deceased members' dependents (if eligible). Unlimited outpatient care is provided in service facilities. In civilian facilities, however, the law extends essentially to hospital care only for wives and children or dependent husbands of members of the uniformed services on active duty for a period greater than 30 consecutive days. Outpatient care in the civilian program is strictly limited to maternity care and bodily injury. The term "uniformed services" applies not only to the Army, Navy, Marine Corps, and Air Force but also to the Coast Guard and to commissioned members of the Public Health Service and Coast and Geodetic Survey.

Only a slight change can be noted in the medical care rendered in service facilities from that which has been traditionally available. Medical care available in civilian facilities, however, is an entirely new development, and it is this part of the program that I wish specifically to discuss.

Executive Director, Office for Dependents' Medical Care, Office of the Surgeon General, U. S. Army, Washington, D. C.

Read before the Section on Military Medicine at the 106th Annual Meeting of the American Medical Association, New York, June 5, 1957.

The law designates the Secretary of Defense to administer the program and to prepare a directive in conjunction with the Secretary of Health, Education, and Welfare. The Secretary of Defense delegated his authority for operation of the program to the Secretary of the Army who redelegated this authority through the Army staff to the surgeon general of the Army. Inasmuch as this was an entirely new and somewhat foreign function to that performed within his office, and because it concerned medical care for dependents of members of the other six services, the surgeon general established an almost autonomous Office for Dependents' Medical Care, headed by an executive director.

The law was signed by the President on June 7, 1956, to be effective on Dec. 7, 1956. An interagency committee, under the supervision of the Assistant Secretary of Defense (health and medical), was established to prepare implementing instructions, definitions, delineations, extensions, restrictions, and procedures considered necessary to administer the program. This committee sought and utilized the advice of civilian representatives, notably those of national organizations (American Medical Association, American Hospital Association, Blue Cross Commission, Blue Shield Commission, and the insurance industry). The deliberations of this committee were incorporated in a document entitled "Joint Directive for Implementation of the Dependents' Medical Care Act" which was officially signed on Oct. 18, 1956, by the Secretary of Defense and the Secretary of Health, Education, and Welfare. This directive is the basis of all actions for administering the program.

The program was placed in operation on the effective date (Dec. 7) in the 48 states, Alaska, Hawaii, Puerto Rico, and the District of Columbia. Contracts were in force, with the Blue Cross Commission and the Mutual Benefit, Health and Accident Association of Omaha acting as fiscal administrators for hospitals within designated geographical areas. With a few exceptions, contracts were in effect in all states, Alaska, Hawaii, Puerto Rico, and the District of Columbia with the medical association of the area and/or a fiscal administrator for payment of physicians' claims. The medical associations as well as the Blue Shield organizations of Ohio and Rhode Island, for reasons of their own, decided not to participate in the program. Neither state, however, objected to the government making arrangements for a fiscal administrator to handle claims by physicians participating in the program. Contractual arrangements were made with Mutual Benefit, Health and Accident Association of Omaha to pay physicians in both of these states. Alabama, Hawaii, and Idaho, for various reasons, had difficulty in arranging for a fiscal administrator to meet government standards. Medical associations of these states readily entered into contractual arrangements, and questions concerning the fiscal administrator were expeditiously resolved. In Maine, the inability of the local Blue Shield organization to enter into contractual arrangements had to be resolved by action of the Maine legislature. In the meantime, the program was fully in effect in these six states, and physicians' claims were promptly paid by the commanding generals of the Army area under whose jurisdiction the state or territory was located. The Army commands are experienced in this field because for many years they have handled physicians' and hospitals' claims for army active-duty personnel who became injured or ill away from their stations.

Financial Aspects of Program

During the implementation of the program, it was considered necessary and appropriate that physicians' fee schedules be developed. The interagency committee prepared from the California schedule a list of items applicable to the program and forwarded a blank schedule to the various state medical associations with a request that a maximum fee (based on the medical practice within the state) be developed for each item which would represent the charge to an individual with an income of approximately $4,500 per year. More than 80% of the members of the uniformed services earn less than this amount. It was intended that physicians charge their usual fees and not exceed in any instance the maximum schedule unless a special report of unusual circumstances was made. This schedule was to be negotiated with representatives of the government at a later date. This negotiation was accomplished in late October and November, 1956, in the Office for Dependents' Medical Care by teams comprised of a physician, a certified contracting officer, a lawyer, and an auditor. The teams met with representatives of the states and territories and carefully reviewed each item to assure that consideration had been given by the committees within the states to the criteria which had been furnished. The state medical associations were given the right to submit separate schedules for different areas within their jurisdiction; however, none did so. No attempt was made to standardize the fees nor were comparisons of states' submissions made during the entire negotiation period. The negotiated schedules had wide and unexplainable variations. The nomenclature of the items contained in the fee schedule did not mean the same to all concerned. How much service was included for the fee was a difficult problem, particularly in orthopedic categories. There were and still are many problems in connection with the fee schedules.

The program has been in effect more than six months. Statistics available are incomplete because of necessary and customary delays in billings and transmissions. Some facts have been compiled from claims submitted to date, and while this information in many cases represents small samples they indicate a trend of the program.

Data compiled from 21,363 cases indicating type of care (principal procedure or operation) revealed that medical and pediatric visits comprised 23.3%; maternity care cases, 47%; tonsillectomies, 11.6%; genitourinary disorders, 6.7%; abdominal operations, 3.8%; injuries, 2%; tumors, 1.9%; and others, 3.7%.

The volume of business data was compiled as of May 22, 1957. There were 64,721 hospital claims at total cost to government of $6,542,407. The average cost of hospital claims was $101.40. There were 310,660 hospital days listed at total cost to government of $21.06. (Patients paid approximately $1,682,746 additionally.) There were 73,689 physicians' claims at total cost to government of $5,048,000. The average cost of physicians' claims was $68.50. A sample calculation of per diem and per case costs to government was cost of patient day (hospital and physician), $50; cost per case (hospital and physician), $250.

Twenty per cent of the participants in the program were males, and the majority of these were children. Eighty per cent of the participants were females. Twelve per cent were under 1 year of age; 22% from 1 to 13 years; 14% from 14 to 19; 38% from 20 to 29; 12% from 30 to 39; and 2% over 40. Forty-two per cent resided apart from their sponsors because of the exigencies of service.

In service distribution, dependents of Army personnel comprised 24.6%; of Navy and Marine Corps personnel, 30.8%; of Air Force personnel, 42.5%; and of Public Health Service personnel, including Coast Guard and Coast and Geodetic Survey, 2.1%

Problems in Administration of Program

Since the inception of the program, there have been literally thousands of questions in the indefinite areas. In maternity care alone there were many questions concerning charges which arose as a result of the various developments, changes, and occurrences during the management of the period of pregnancy. These questions have been met with the best knowledge available and, in general, the program is operating on principles which have been rather universally accepted.

Emergency care of acute emotional disorders (care of nervous and mental diseases is specifically prohibited by the law) has been a difficult problem. In general, the program now allows up to 21 days' care in such emergencies with reasonable extensions if additional time is required to (1) reach a responsible sponsor, (2) obtain acceptance in a state institution, (3) complete short-term treatment if cure or remission will allow return home, and (4) determine by diagnosis if long-term care is needed. Treatment of tuberculosis is allowable under the program if the case is contagious, acute, or amenable to surgery. Medical care in a hospital for chronic diseases is permissible if an acute exacerbation occurs or if the physician believes certain treatment will contribute to the life, health, or well-being of a patient. Likewise, elective surgery which the physician considers indicated and is not desired by a patient solely for cosmetic or other reasons is considered to be a proper charge to the government under the program. Great dependence is thus placed on the physician's judgment.

In the operation of this program, it is imperative that the Army, Navy, Air Force, and Public Health Service be kept fully informed and, in fact, conjointly make many of the decisions. A liaison committee has existed since the operation of the program. A formal meeting is held once each month and daily contacts are made concerning problem cases. It is also necessary that the A. M. A., A. H. A., and American Dental Association be thoroughly informed concerning the program and that these organizations participate in many decisions. The Medical Care Committee of the A. M. A. periodically meets with representatives of the Office for Dependents' Medical Care. At these meetings, consideration is given to the broad problems which have arisen. A permanent contact has been selected in the Washington office of the A. M. A. in order that daily problems which might affect the profession can be discussed. The A. H. A. also has a committee which meets periodically with the Office for Dependents' Medical Care on problems affecting hospitals of the nation. Almost daily communication is maintained with its Washington office.

Many meetings and discussions as well as detailed studies have been conducted with the dental profession since the inception of the program because the problem of adjunctive dental care has been one of the most difficult. Very close contact, of course, is maintained at all times with the Blue Cross and Blue Shield commissions and with the various insurance companies which are contractors under the program.

The Dependents' Medical Care Program is not completely subsidized by the government. A patient has certain monetary responsibilities, and the government assumes the remainder. A physician may charge the government more than the scheduled fee if he can reasonably justify the additional charge. However, he cannot charge the patient more than the amount stipulated in the law or directive. The program, except for the Office for Dependents' Medical Care, is operated by civilian agencies whose civilian function is to operate similar programs. There has been generally good acceptance of the program by physicians, hospitals, and medical and hospital organizations. While the law provides for the restriction of the right of dependents to use civilian physicians and facilities in any area, no such restriction has been made or even proposed. The eligible dependent (wife, children, and dependent husband of active-duty members) has free choice between uniformed service and civilian facilities.

There are evidences of benefit to morale within the services which, at this early date, can be based only on chance remarks. Information concerning the program is reasonably well disseminated. On the whole, the program now appears to be a workable one which fits well within the framework of our democratic ideals. And whatever success it may now claim is due to the combined efforts of the national and state medical and hospital associations, the various insurance plans, both profit and nonprofit, and the support and participation of the physicians and hospitals of the nation. It is hoped that the program's future will be such that it can serve a most useful and needed service for our country both in time of peace and during any mobilization.

BENZATHINE PENICILLIN G IN THE PREVENTION OF STREPTOCOCCIC INFECTIONS

Capt. Alton J. Morris (MC), U. S. A. F.
and
Charles H. Rammelkamp Jr., M.D., Cleveland

The effectiveness of benzathine penicillin G in preventing streptococcic pharyngitis was determined during an epidemic of this disease among military personnel at an air force base. A single intramuscular injection was given to each of 741 men, representing about 10% of the exposed population. Three dosage levels were tried, and all were equally effective in eliminating group A streptococci from the throat in carriers, while men who had received a placebo injection continued to harbor the organisms. The duration of protection, however, varied with the dosage. The first streptococcic infections began to occur as early as the 8th day after injection in 240 men who had received 300,000 units, while in 246 men who had received 1,200,000 units the first illnesses were observed on the 44th day. It appeared that 1,200,000 units of benzathine penicillin G protected the individual for approximately six weeks.

Benzathine penicillin G is employed for the prevention of streptococcic infections in rheumatic patients. For this purpose it is recommended that 1,200,000 units be given by intramuscular injection at monthly intervals.[1] Although this prophylactic regimen appears to be adequate for the prevention of streptococcic infections and recurrences of rheumatic fever,[2] there is little information concerning the duration of protection afforded by this and other doses of benzathine penicillin G. Since the incidence of reactions to benzathine penicillin G is related to the amount injected,[3] further information concerning the duration of protection afforded by various amounts of benzathine penicillin G is required. The present report describes the results of such a study and, in addition, presents data on the effectiveness of a single injection of benzathine penicillin G on the elimination of group A streptococci from the tissues of the oropharynx and tonsils.

Methods and Results

Oropharyngeal cultures were streaked on 5% sheep blood agar, and after 18 hours incubation colonies exhibiting beta hemolysis were isolated. Serologic identification of these isolates was performed by standard techniques.[4]

In November, 1954, the school area at Warren Air Force Base, Wyoming, became involved in a rapidly increasing epidemic of streptococcic pharyngitis. When the hospital admission rates for streptococcic infections reached 16 per 1,000 per week, benzathine penicillin G was administered as prophylaxis to approximately 25% of the airmen in each of six student squadrons. The number of men who received prophylaxis totaled only 10% of the entire student population. By administering the drug to such a small fraction of the personnel, it was believed that the epidemic would be relatively unaffected so that when the period of protection had passed those men who had received prophylaxis would soon acquire infections.

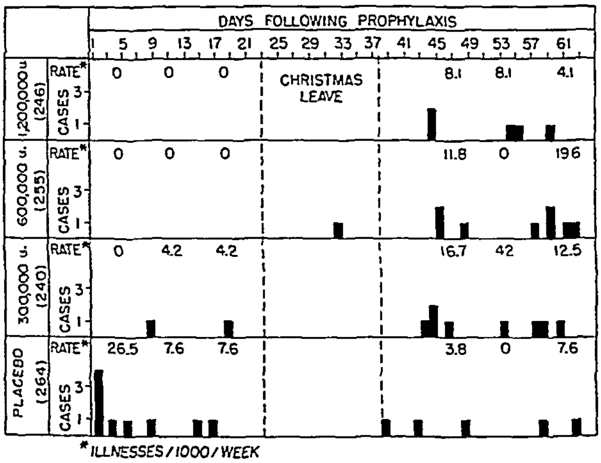
To determine the duration of protection afforded by benzathine penicillin G against streptococcic infection, three different doses were employed. As

---

From the Streptococcal Disease Laboratory, Francis E. Warren Air Force Base, Wyoming, and the departments of preventive medicine and medicine, Western Reserve University School of Medicine.

shown in the figure, each group receiving penicillin was composed of approximately 250 airmen, whereas saline solution was administered to 264 men who served as controls. During the subsequent nine weeks, all airmen reporting to sick call with fever and respiratory symptoms or showing exudative tonsillitis or pharyngitis were admitted to the hospital. Oropharyngeal cultures were obtained from each patient. In the figure the time of occurrence of each illness characterized by exudative tonsillitis or pharyngitis and a positive culture for group A streptococci is indicated.

During the first week after the administration of prophylaxis no streptococcic illnesses as defined above were observed in the three groups receiving penicillin, whereas the weekly rate for the control group was 26.5. During the second and third weeks two infections were observed among the men receiving 300,000 units, but none developed in the men receiving larger amounts of penicillin. Since between the 22nd and 38th day after prophylaxis most of the men were not on duty, the data concerning the number of infections during this period are not reliable. One illness did develop among the men receiving 600,000 units. After the return of the population after Christmas vacation, illnesses occurred in all four study groups. The first illnesses in the group which received 1,200,000 units developed on the 44th day after injection.



Comparative effect of various amounts of benzathine penicillin G in prevention of streptococcic infections.

Table 1 shows the results of cultures of the oropharynx obtained just prior to prophylaxis and two, six, seven, and nine weeks later. Group A streptococci were isolated from 13 to 22% of each group prior to prophylaxis. At each subsequent survey there was little change in the carrier rate of the control group. In contrast, at two weeks no positive cultures were obtained in the groups receiving 1,200,000 or 600,000 units. There was also a tenfold reduction in the carrier rate in the group receiving 300,000 units. At the time of the sixth-week survey, a few positive cultures were recorded from the two groups receiving the largest amounts of penicillin. At the ninth week the carrier rates were approaching the levels observed prior to prophylaxis, but they were still considerably lower than that observed in the control group.

Since the carrier rate at any of the follow-up examinations was composed of both chronic carriers and individuals who had recently acquired a new organism, it is difficult to interpret the results of these culture surveys. In table 2 are presented the results of all cultures obtained during the nine-week period of observation in those individuals who harbored a group A Streptococcus initially and whose organism was successfully typed serologically. In this selected group it is possible to determine the effect of prophylaxis on elimination of the organisms and, in addition, to ascertain the approximate degree that the chronic carrier contributes to the observed carrier rates.

Table 1.—*Carrier Rates for Group A Streptococci Before and After Various Amounts of Benzathine Penicillin G*

Prophylaxis Units	Men, No.	% of Each Group from Which Group A Streptococci Isolated Prior to Prophylaxis	% of Each Group from Which Group A Streptococci Isolated. Weeks After Prophylaxis			
			2nd	6th	7th	9th
1,200,000	246	13	0	2	5	8
600,000	255	14	0	2	3	9
300,000	240	20	2	6	8	10
Placebo	264	22	19	23	24	22

All three doses of benzathine penicillin G appeared to be equally effective in the elimination of group A Streptococci from the throat. In from 86 to 93% of the carriers in each of the three selected treatment groups no positive cultures were obtained during the follow-up period. Only one new acquisition was definitely identified from the penicillin groups. Failure to eliminate the infecting type of Streptococcus occurred in only five individuals, two in the group receiving the largest dose of penicillin and three in the group receiving 300,000 units. The two individuals in the group receiving 600,000 units whose cultures showed an organism which could not be typed may represent failure to eliminate the Streptococcus, since other studies have demonstrated that as the carrier state progresses, most streptococci become nontypable.[5]

Table 2.—*Effect of Benzathine Penicillin G on Group A Streptococcic Carriers* During Nine Weeks After Administration*

Prophylaxis, Units	Carriers, No.	Culture After Prophylaxis			
		Negative	Positive		
			Same Type	New Type	Not Typable
1,200,000	22	19	2	1	0
600,000	28	26	0	0	2
300,000	33	30	3	0	0
Placebo	50	10	31	5	4

* Includes only those individuals whose group A streptococci isolated before prophylaxis could be classified according to serologic type.

In contrast to the groups receiving penicillin, only 20% of the carriers in the control group failed to show group A streptococci during the follow-up survey. From 70%, either the infecting type or a nontypable organism was isolated, and in 10% a new type was identified. This latter group of five individuals may represent patients with new infections. Only one such isolation was made in the 83 patients who received penicillin.

Comment

The data obtained in the present study showed that after the administration of 300,000 units of benzathine penicillin G, streptococcic infections began to occur as early as the eighth day, whereas after 600,000 and 1,200,000 units the first illnesses were observed on the 32nd and 44th days respectively. Since many in the four experimental groups were on leave during the fourth and fifth weeks, it cannot be concluded that complete protection was afforded throughout this period. In order to gather further information, data collected on all individuals who had received benzathine penicillin G at Warren Air Force Base, Wyoming, over a period of several years were analyzed. This included a previously reported mass prophylaxis survey[3] and a more recent prophylaxis study by Davis and Schmidt.[6]

In addition, benzathine penicillin G had been administered to a large number of patients with streptococcic infections who were subsequently observed for signs of a new infection.[7] These collected data are summarized in table 3. A total of 935 individuals have been given 1,200,000 units of benzathine penicillin G, and in this group the earliest time clinical illness was recognized was 44 days later. After the administration of 600,000 units, the earliest infections developed 26 days after infection, whereas with 300,000 units there was little protection after the eighth day. In these studies the benzathine penicillin G employed belonged to a single lot number. Several years later, employing a new lot of penicillin, Davis and Schmidt[6] administered 900,000 units to 2,214 men during an epidemic. In this instance, the earliest streptococcic illness occurred on the 15th day, but there appeared to be a high degree of protection for at least three weeks. Assays of the potency of several samples of this lot failed to reveal any appreciable deterioration. Samples of the penicillin used in the present study were not available for analysis.

From the present study it appears that 1,200,000 units of penicillin protected the individual for approximately six weeks. Since 900,000 units in the study by Davis and Schmidt[6] did not confer complete protection for four or five weeks, it is obvious that additional data are required before precise recommendations can be made for the management of patients who have rheumatic heart disease or who have experienced an attack of rheumatic fever. Further studies on the duration of protection against streptococcic infections provided by 1,200,000 units of benzathine penicillin G are justified, since in the management of patients with rheumatic fever an injection every six weeks would hold distinct advantage over an injection once a month. Judging from illnesses developing after administration of 1,200,000 units of penicillin, it appears that such prophylaxis affords considerable protection for at least six weeks. In the protection of rheumatic patients, however, inapparent infections may play an important role in the development of recurrences, and considerable more bacteriological, immunological, and clinical data are required for final conclusions in relation to prophylaxis in patients with rheumatic fever.

Benzathine penicillin G has also been employed for the control of epidemics of streptococcic infections among military personnel and in the treatment of streptococcic infections.[8] In both of these instances the eradication of the organism is a most important feature of therapy. In this regard, it is interesting to recall that there were no discernible differences between the three dosage regimens employed, all being about 90% effective. Why penicillin fails to eliminate the organism in some patients or carriers is not known. The importance of these persistent carriers in the initiation of new outbreaks is unknown; but in patients with streptococcic infections, failure to eliminate the Streptococcus results in attack rates of rheumatic fever comparable to those observed in untreated patients.[7]

Table 3.—*Summary of Experience at Warren Air Force Base, Wyoming, with Benzathine Penicillin G as Prophylaxis Against Streptococcic Infections*

Benzathine Penicillin G, Units	Men, No.	No Developing Illness During Weeks After Injection						
		1st	2nd	3rd	4th	5th	6th	7th
1,200,000	935	0	0	0	0	0	0	4
600,000	874	0	0	0	1	1	1	3
300,000	240	0	1	1	..	..	..	4
None	563	9	5	3	1	1	3	2
900,000*	2,214	0	0	3	5	11	17	..
None*	483	14	5	8	1	2	2	..

* Data from Davis and Schmidt.[6]

Summary

Benzathine penicillin G was administered as a single intramuscular injection in doses of 1,200,000, 600,000, and 300,000 units to 246, 255, and 240 men, respectively, during an epidemic of streptococcic pharyngitis in a military population. The duration of protection provided by each dose as determined by the development of exudative pharyngitis due to group A streptococci was six to seven weeks, four to five weeks, and one to two weeks respectively. All three dosage regimens were equally effective in eradicating streptococci from carriers. The data indicate that benzathine penicillin G is a valuable agent in the control of streptococcic disease.

This investigation was conducted under the sponsorship of the Commission on Streptococcal Diseases, Armed Forces Epidemiological Board, and was supported by the offices of the Surgeons General, departments of the Army and Air Force, Washington, D. C.

The benzathine penicillin G used in this study was supplied as Bicillin through Dr. Edward F. Roberts, Wyeth Laboratories, Inc., Philadelphia.

REACTIONS FROM MULTIPLE INJECTIONS OF BENZATHINE PENICILLIN G

Major Robert W. Sherwood, Lieut. Col. Christian Gronbeck, (MC), U. S. Army
and
Floyd W. Denny Jr., M.D., Cleveland

A comparison was made between two dosage plans for the intramuscular administration of benzathine penicillin G as prophylaxis against rheumatic fever, nephritis, and streptococcic infections in the armed forces. One group of 1,567 men received 600,000 units every four weeks; the other group, of 1,708 men, received 900,000 units every six weeks. No reactions of the anaphylactoid type occurred, but during the six months of the study 16 men were hospitalized for urticaria, angioneurotic edema, or joint symptoms; 11 were hospitalized after the first injection, 4 after the second, and 1 after the third. Most (11) of these severer reactions occurred after the injection of 900,000 units, but the probability of reaction to subsequent doses decreased in both groups, and prolong the interval between injections did not affect the probability of a reaction. Because few streptococcic infections were seen, this study did not test the effectiveness of the prophylaxis, but it did demonstrate the safety and feasibility of administering benzathine penicillin G in this way.

The increasing number of reactions to penicillin that are being reported has focused attention on the possibility that large segments of the population may be sensitized to this antibiotic by repeated injections. This problem is particularly important in the use of penicillin for the control of streptococcic infections in patients who have had rheumatic fever and for the control of epidemics of streptococcic infections, rheumatic fever, and nephritis in the armed services. In recent years interest in penicillin preparations which are slowly absorbed from intramuscular deposits has increased. A relatively new depot preparation, benzathine penicillin G, may prove to be an ideal prophylactic agent. At present, information is meager concerning the duration of protection in relation to size of dose as well as incidence of reactions after various doses and repeated injections.

This study was designed to obtain further information concerning the prophylactic effect of repeated injections of benzathine penicillin G, in two different dosage schedules, on prevention of streptococcic disease and also on the incidence of sensi-

(Lieutenant Colonel Gronbeck); and Assistant Professor of Preventive Medicine and Pediatrics, Western Reserve University School of Medicine (Dr. Denny). Colonel Gronbeck is now Director of Medical Division, Walter Reed Army Institute of Research, Washington, D. C.

tivity reactions occurring during such regimens. Since the incidence of streptococcic infections was too low for evaluation, this report will deal only with reactions.

Methods

Four Army battalions in one combat command, living in similar quarters and under nearly identical training conditions, were chosen to participate in this investigation, which lasted from Oct. 15, 1955, to April 15, 1956. These battalions were training at greater than authorized strength; therefore, additional personnel joining the organization were minimal. Two battalions totaling 1,567 men were placed on a regimen of 600,000 units of benzathine penicillin G (Bicillin) every four weeks for a total of six injections, and two battalions of 1,708 men were placed on a regimen of 900,000 units every six weeks for a total of four injections. These doses and time intervals were selected because preliminary studies showed that 600,000 units of benzathine penicillin G protected against streptococcic infections for three to four weeks and 900,000 units for somewhat longer periods.[1] Larger doses (1,200,000 units) were omitted because of the high incidence of reactions after one injection.[2]

Personnel who were not available for the first injection periods were added to the recipient group as late as the fourth period in the 600,000-unit group and third period in the 900,000-unit group. This procedure allowed a larger number of personnel to participate but decreased the percentage of participants completing the full series of injections. Penicillin was administered intramuscularly in the upper outer quadrant of the buttocks, in alternate sides at each injection.

Before the first injections were given, the purpose of the study was explained to the men, and they were encouraged to report previous reactions to penicillin. Those who stated that they had had previous reactions were individually interviewed. Men with definite histories of skin rashes or joint reactions were then removed from the study group. The soldiers receiving prophylaxis were directed to report on sick call should they develop any form of skin reaction or joint pain or swelling at any time. In addition, before each injection, all individuals were questioned regarding occurrence of reactions after the previous injection. All personnel with reactions were seen by one of two physicians who evaluated and described the condition on a reaction history form. Urticaria, angioneurotic edema, and joint pain and/or swelling were classified as probable benzathine penicillin G reactions; other skin rashes and systemic reactions (fever, headache, nausea, vomiting, and general malaise) were classified as possible reactions.

All men with probable or possible reactions were excluded from further participation in the study. In addition, those who had severe, painful, local reactions were removed from the study group for purposes of morale. Observations for reactions continued during the entire six-month period of this investigation. In order to prevent the men from receiving agents not administered as part of the investigation, all antibiotics and chemotherapeutic agents were removed from the dispensaries serving the study battalion on the day the study began.

Results

Table 1 shows the number of personnel available at each injection period in the 600,000-unit and 900,000-unit groups, respectively, and also the cumulative number of personnel removed because of a history of reactions to penicillin prior to this study and because of reactions to benzathine penicillin G during the study. The group remaining after the removal of the individuals with reactions was considered the group eligible for injections. Table 1 includes the number and percentage of those groups which actually received benzathine penicillin G at each of the injection periods. It can be seen that the participation was 92% at the first scheduled injection in October and at least as high as 75% at all later scheduled injections. The higher percentage of participants at the beginning was due primarily to starting the study at a time when the maximum number would be present. The lower percentage of participation at later periods was accounted for mainly by the absence of men from the post because of attendance at service schools, leave, or prolonged field duty.

* Slight fluctuations in total numbers were due to transfers in and out of study units

† History of penicillin reaction previous to present study; increase in numbers was due to new additions to study at each period of injection.

‡ Benzathine penicillin G reaction during this study.

§ Number eligible for injections is total population minus all individuals with penicillin reactions.

The units selected for prophylaxis contained 3,275 men of whom 214, or 6.5%, gave a history of previous reaction to penicillin and were eliminated from the study. Included among the 214 men were 170 who were excused from the initial injection and 44 who reacted after their first injections and then recalled a penicillin reaction at some previous date. Data on none of these 214 individuals are included in the benzathine penicillin G reaction tables.

Table 2 shows the cumulative probability of reactions after multiple injections of benzathine penicillin G. In this table the reactions are classified as probable or possible, 79% were considered probable and 21% possible. In the remainder of the paper the rates cited will include both classifications. It was found that the probability of reacting to the first injection was much greater than that of reacting to later injections. The same was true in both dosage schedules. In the 600,000-unit group, the probability of reacting to the first injection was 0.031, or 3.1%, and to the second was 0.011, or 1.1%. In the 900,000-unit group, the probability of reacting to the first injection was 0.039, or 3.9%, and to the second was 0.012, or 1.2%. In both groups, after the first two injections, the probability of reacting was slightly lower and remained relatively constant for the remainder of the injections. The cumulative probability of reacting to repeated injections of benzathine penicillin G was found to be 0.061 after six injections of 600,000 units and 0.058 after four injections of 900,000 units.

4	765	4	0	4	0.995	0.942	0.005	0.058

* Probable reactions were urticaria, angioneurotic edema, and joint pain and/or swelling. Possible reactions were other skin rashes and systemic reactions (fever, headache, nausea, vomiting, and general malaise).

† Probability of not reacting = number receiving injections without reacting ÷ total number receiving injections.

‡ Cumulative probability of not reacting = cumulative probability of not reacting after one injection × probability of not reacting after next injection (Example: 0.969 × 0.989 = 0.958).

§ Probability of reacting = 1.000 — probability of not reacting.

‖ Cumulative probability of reacting = 1.000 — cumulative probability of not reacting.

There were few complaints of pain at the injection site and only five individuals were removed from the study because of moderately severe local reactions manifested by pain, swelling, and redness. No abscesses occurred and no one was hospitalized because of local reaction. These few local reactions are not included in the reaction statistics.

In general, the systemic reactions were mild. No reactions of the anaphylactoid type occurred. During the study period 16 individuals were hospitalized for urticaria, angioneurotic edema, or joint symptoms, 5 were from the group receiving injections of 600,000 units, and 11 were from the group receiving injections of 900,000 units. Eleven were hospitalized after the first injection, 4 after the second, and 1 after the third. All patients were treated with orally given tripelennemine (Pyribenzamine) citrate. In addition, one patient was given one injection of aqueous epinephrine and corticotropin (ACTH) for urticaria 14 days after he had received benzathine penicillin G. A second patient was given one injection of aqueous epinephrine and cortisone for one day for urticaria and joint swelling. Usually all symptoms and signs disappeared within two or three days after the start of treatment; however, one patient was hospitalized for 40 days because of recurring urticaria.

The interval between the time of injection and onset of reaction was not appreciably different in the two dosage schedules; therefore, the two will be considered together. Sixty-eight per cent occurred during the first week and 88% by the end of the second week. A few reactions attributed to benzathine penicillin G became apparent as late as eight weeks after the injections.

The effect of prolonging the interval between injections in both dosage schedules is demonstrated in table 3. Here the percentage of those who reacted after injections given without interruption is compared with the percentage of those who reacted after the administration of benzathine penicillin G with one or more additional intervals between in-

TABLE 3.—*Effect of Prolonging Interval Between Injections on Reaction Rates in Soldiers Receiving Benzathine Penicillin G on Two Dosage Schedules*

No. of Injections Received	Distribution of Injections*	No. of Men Receiving at Least Specified No. of Injections†	Reactors No.	Reactors %
600,000 units every four weeks

	Interrupted	236	1	0.4
3	Uninterrupted	905	1	0.1
	Interrupted	264	1	0.4
4	Uninterrupted	765	4	0.5

* Uninterrupted means the indicated number of injections was given at the defined intervals; interrupted means that the benzathine penicillin G was given with one or more additional intervals between injections.

† Individuals classified as having received at least a specified number of injections may or may not have received more; those that did are included later in the table also.

jections. It can be seen that, in this study, the percentage of those reacting did not increase when the time between injections was increased.

Comment

Injectable benzathine penicillin G has been shown to be effective in the eradication of the group A Streptococcus from the throat and in the prevention of streptococcic infections and their complications, rheumatic fever and nephritis.[3] This drug has the advantage of being so slowly absorbed that single doses of 600,000 units or more will produce blood levels effective for the prophylaxis of streptococcic infections for two to four weeks.[1] Such an agent should be ideal for use in the control of streptococcic infections in military units or in patients with rheumatic fever, but the possibility of encountering serious sensitivity reactions, particularly if injections are repeated in the same individual, has led to caution in its widespread use. In the study here described, 11,962 intramuscular injections of benzathine penicillin G, either 600,000 or 900,000 units, were given to 3,179 Army personnel without the occurrence of a single fatal or anaphylactoid reaction. Thirty-seven per cent of those in the 600,000-unit group received all six injections and 46% of those in the 900,000-unit group received all four injections. The reaction rates did not differ significantly in the groups receiving either 600,000 or 900,000 units.

When those with reactions after each injection were excluded from the study, the probability of reacting decreased markedly after the first injection and remained low for the remainder of the injections. It is possible that the reactions after the later injections represent sensitization induced by previous injections, but the numbers were small and did not constitute a problem in this study. The longest interval between injections was four and one-half months, and prolonging the interval to this extent did not change the reaction rates. If it can be assumed that the men who gave a history of previous penicillin reactions were sensitive to benzathine penicillin G, then the data in this study indicate that most individuals (85%) sensitive to the drug can be identified by an adequate history and reactions after an initial injection.

Reported reaction rates after injections of benzathine penicillin G vary greatly. Brooks and Moe,[4] in a study of naval recruits, and Smith and his coworkers,[5] in a study in venereal disease clinics, report reaction rates of less than 1% after a single injection; on the other hand, Chamovitz and others [3c] reported a reaction rate of 5.1% in young airmen after one injection. Stollerman, Rusoff, and Hirschfeld,[6] in a study in young persons with rheumatic disease who received an average of 12 injections per patient, reported that 3.2% of patients suffered reactions. The reaction rates of approximately 3.5% after one injection and approximately 6% after four or six injections in the present report, therefore, appear high. The cause for this discrepancy is unknown. It is possible that some of the increase can be explained by the inclusion of minor or insignificant reactions or the greater likelihood of detecting reactions in the particular group in this study. It is also possible that the incidence of penicillin reactions may be higher in adults, as reported here, when compared with the lower incidence in children, as reported by Stollerman and his group.

This study was originally designed to study the efficacy of benzathine penicillin G as a prophylactic agent against streptococcic infections. The incidence of these infections was too low for evaluation; therefore, these data are not included in this report. It is of interest, however, that the incidence of gonorrheal infections was markedly reduced in the treated group; one of the 3,275 men who received benzathine penicillin G developed gonorrhea, while 192 of 13,000 untreated men in the same Army division developed this disease.

Since, in this study, most individuals sensitive to benzathine penicillin G could be detected by a history of a previous reaction to penicillin or a reaction to an initial injection, reactions, in general, were not serious, and rates did not change when the intervals between injections were prolonged, it seems proper to conclude that the routine use of repeated injections of this drug as a prophylactic agent in large groups is not only feasible but safe.

Summary

The rates and severity of reactions after repeated intramuscular injections of benzathine penicillin G were studied in four Army battalions. Two dosage regimens were used, 600,000 units every four weeks (1,567 men) and 900,000 units every six weeks (1,708 men). No fatal or anaphylactoid reactions were encountered. The cumulative probability of reacting was almost identical, 0.061 (6.1%) in the 600,000-unit group and 0.058 (5.8%) in the 900,000-unit group. When those with reactions were excluded the probability of reaction decreased markedly in both groups after the first injection, and prolonging the interval between injections did not change the reaction rates. It was concluded that the use of repeated intramuscular injections of benzathine penicillin G was a feasible and safe procedure.

2109 Adelbert Rd. (6) (Dr. Denny).

This investigation was conducted under the sponsorship of the Research and Development Division, Office of the Surgeon General, Department of the Army, Washington, D. C., and the Commission on Streptococcal Diseases of the Armed Forces Epidemiological Board.

Dr. Charles H. Rammelkamp Jr. and Col. Kenneth A. Brewer assisted in planning this study, and Dr. Arthur S. Littell did the statistical analyses.

The benzathine penicillin G (Bicillin) used in this study was supplied through Dr. Edward F. Roberts of Wyeth Laboratories, Philadelphia.

TREATMENT OF MYASTHENIA GRAVIS

PROLONGED ACTION WITH MULTIPLE-DOSE TABLETS OF NEOSTIGMINE BROMIDE AND MESTINON BROMIDE

Robert S. Schwab, M.D., Boston, Kermit E. Osserman, M.D., New York
and
J. Edward Tether, M.D., Indianapolis

The anticholinesterase drugs used in treating myasthenia gravis do not have a prolonged action. The ordinary dosage forms must be taken frequently during the day, and some patients have had to be awakened repeatedly during the sleeping period for medication. New dosage forms (slow-release tablets) have therefore been developed. Neostigmine bromide in the form of slow-release tablets was tried in 85 patients, 54 of whom continued to take this form by preference at the conclusion of the experiment. Mestinon bromide in the form of slow-release tablets was similarly tried in 109 patients, 82 of whom continued to take this form at the conclusion of the experiment. The average duration of action of the slow-release Mestinon tablet was approximately six hours. There were many individual differences in the responses to these dosage-forms, and some patients preferred to take the slow-release tablets only at bedtime. Their greatest value was in eliminating the need of frequent interruptions of sleep.

The most important advance in the treatment of myasthenia gravis undoubtedly was the discovery by Dr. Mary Walker[1] in 1934 that neostigmine injections temporarily overcame the symptoms. Certainly the next step was the introduction by Everts[2] in 1935 of 15-mg. neostigmine tablets to be given orally. Both the injection and the tablet last effectively only one to three hours. In severe cases, therefore, frequent dosage is mandatory, such as every two hours day and night. This means inconvenience during the waking hours and extreme interruptions of sleep, or dangerous exacerbations of symptoms if the patient sleeps through. Prolonging the parenteral effect by the use of oil was tried in 1939 by one of us (R. S. S.),[3] but the absorption was so uncertain in every instance that either serious overdosage or the reverse occurred. The death of one patient in a cholinergic crisis while on maintenance therapy with the oil preparation caused complete abandonment of this technique of administration.

Mestinon bromide, an analogue of neostigmine which is the dimethylcarbamate of 3-hydroxy-1-methylpyridinium bromide, was made available for the treatment of myasthenia gravis in 1953. It is now available in scored 60-mg. tablets, each of which is roughly equivalent to 15 mg. of neostig-

---

mine bromide. Mestinon has less gastrointestinal side-effects than neostigmine and in some patients has a longer action. Many patients, however, must take frequent doses during the day, and some must be awakened for doses during the sleeping period.

In recent years new dosage forms of various drugs have been constructed to permit slow release. Since a patient with myasthenia gravis requires frequent doses during the daytime hours, it was suggested to the manufacturers that some form of prolonged-action tablet be prepared. Two sizes of neostigmine bromide and Mestinon bromide tablets were made available to us. In the case of neostigmine, the equivalent of three regular 15-mg. tablets, or a total dose of 45 mg., was contained in the full-strength tablet. (This tablet should not be confused with an enteric-coated or delayed-action type that passes through the stomach, its coating insoluble in the acid medium. Such tablets lose the protection coat in the alkaline small intestine, releasing the constituents as rapidly as an ordinary compressed tablet in the stomach. Their main function is to avoid contact of the contents with the most sensitive gastric mucosa, as in the case of some patients with aspirin. They may also, if the coating is thick enough, delay final dissolution, so that the absorption comes later than that of an ordinary capsule or tablet. In 1938 one of us [R. S. S.][3] tried enteric-coated neostigmine without any advantage over the usual tablet.) The other tablet of neostigmine was half-strength, containing three doses of 7.5 mg. each or a total dose of 22.5 mg. In the case of Mestinon bromide, there was a full-strength tablet, containing three regular doses of 60 mg. or a total of 180 mg., and a half-strength tablet, containing three doses of 30 mg. or a total dose of 90 mg.

Table 1.—*Results with Prolonged-Action Neostigmine Bromide Tablets in Eighty-Five Patients*

Clinic	Max. per Day	Min. per Day	Av. per Day	Better than Reg. Med.	Equal	Not So Good	Over-dosage	Total Patients
Boston	12	1	3	23	3	8	3	34
Indianapolis ..	26	1	8	19	6	7	4	33
New York	16	1	5	12	2	4	2	18
Total	26	1	5	54	11	19	9	85

The information we desired to obtain was whether such tablets could provide effective control of myasthenic symptoms over extended periods of time, such as during the entire sleeping hours at night, whether in a given patient they were effective day after day, and whether the total contents approximated the equivalent amounts of drug taken in ordinary tablets. We also sought data as to whether such forms gave smoother absorption than repeated regular doses and whether overdosages or undermedication were complicating factors.

Patients were fully instructed as to the nature of the tablets and their purpose, including the obvious fact that such tablets could not be cut in two. The first trial was to substitute in equivalent amounts the prolonged-action or slow-release tablets for regular ones so as to see in each case how long the effective control lasted. The use of these tablets before retiring at night to avoid the need of waking for a dose of medicine was considered their most important value.

Results

Prolonged Action with Neostigmine Bromide.—In the three clinics in 1956 we administered the slow-release tablets of neostigmine bromide to a total of 85 patients (34 at Massachusetts General Hospital, Boston, 18 at Mount Sinai Hospital, New York, and 33 at Indiana University Medical Center, Indianapolis). Of the 85 patients, 54 are still finding the tablets of such value that they wish to continue with this therapy—a favorable percentage of 65.

The duration of effectiveness of the three-dose type varied from a minimum of 3 hours to a maximum of 12 hours, with an average effectiveness of 6 to 7 hours. In some patients the total amount of drug taken in this manner exceeded that in regular tablets by 33% without evidence of overdosage or better control, suggesting that some of the drug in such cases may escape absorption. In three patients with symptoms of dysphagia, the increased size of the tablet bothered the patients to such an extent that administration was discontinued. In all others this was not a problem.

In some patients the half-strength tablet was adequate for bedtime dosage (the full-strength one causing diarrhea and cramps in the early morning). Other patients preferred regular tablets during the day to give greater flexibility and prolonged-action tablets during the night. In some the prolonged-action tablets worked effectively during the day but were no better than regular tablets, affording only the convenience of fewer doses as an advantage. A few patients felt that the benefit of smoother, more even absorption was sufficiently present so that they preferred to remain on the slow-release neostigmine therapy.

The composite details of the results of administering prolonged-action neostigmine bromide tablets to 85 patients are shown in table 1. In this group of patients, variability in absorption, once satisfactory dosage was established, did not occur. Severe toxic or accumulative effects were not encountered. In no patient was significant failure of absorption encountered (tablets were not passed per rectum).

Prolonged-Action with Mestinon Bromide.—One hundred nine patients, both private and clinic, at Mount Sinai and Massachusetts General hospitals and at Indiana University Medical Center, were transferred to therapy with prolonged-action Mestinon tablets. We were careful to choose 83 patients who had previously been controlled on regular Mestinon bromide tablets, since we did not wish to becloud the clinical results of the new dosage form by using patients who had previously shown a preference for neostigmine (Prostigmin) bromide or ambenonium (Mytelase) chloride. Twenty-six patients who had previously been taking Mestinon bromide in combination with other drugs were also transferred to therapy with long-acting Mestinon bromide; this therapy included the administration of prolonged-action Mestinon bromide tablets in combination with prolonged-action neostigmine bromide (10 patients), with regular neostigmine (6), with ambenonium and regular neostigmine (2), and with ambenonium (8).

The prolonged-action Mestinon bromide tablets were withdrawn in 22 of the 83 patients selected. Sixty-one patients are still on maintenance therapy with prolonged-action Mestinon. These patients have been followed for a minimum period of 1 month and a maximum period of 12 months. The administration of the prolonged-action Mestinon tablets was discontinued in the case of the 22 patients for the following reasons: 1. Ten patients experienced excessive stimulation of the intestinal tract, with other muscarinic side-reactions. These toxic reactions were identical with those of overmedication with regular Mestinon tablets. 2. Seven patients could find no advantage in the prolonged-action Mestinon tablets over the regular tablets. They had been content and well adjusted on the ordinary tablets. 3. Three patients needed odd dosages during the day, only obtainable by taking a portion of the scored tablet; i. e., they needed three-fourths or one and three-fourths or only one-fourth of the regular Mestinon tablet to be well regulated. These patients were not content with the dosage available at present in the prolonged-action tablet. 4. One patient found that the prolonged-action Mestinon tablet was too large for her to swallow and stated that she nearly choked several times on these tablets. She had a peculiar anxiety reaction to large tablets, which is part of her personality complex. 5. One patient, a 32-year-old woman at the New England Medical Center, Boston, was totally unable to absorb any medication from the prolonged-action Mestinon tablets, passing them with her stool unchanged, and they were, therefore, not effective. Subsequently her thymus was removed, and she went into a partial remission. Then she went through the same procedure a second time when prolonged-action Mestinon tablets were administered, these tablets remaining unabsorbed. Her condition can now be effectively regulated by the daily administration of 12 prolonged-action neostigmine tablets, each containing 45 mg.

In the manufacture of the prolonged-action Mestinon bromide tablet, the core is made of an inert material into which the Mestinon is absorbed. This core may appear in the feces, and the patient may fear that the medication has not been assimilated. Assays of these cores recovered from the feces reveal that most, if not all, of the Mestinon has been utilized.

A few patients were satisfied with the action of the regular Mestinon tablets during the daytime hours and preferred taking the prolonged-action tablets only at bedtime. Occasionally, because of the prolonged action, it is not possible to space proper dosages over the 24 hours of the day, so that one dose of regular Mestinon bromide may be required in the late afternoon or the early evening to fill in the hiatus between the awakening and the bedtime doses. Twenty of the 61 patients who are on maintenance therapy with Mestinon bromide use combinations of regular and prolonged-action tablets. Of the 10 patients who have been taking combinations of prolonged-action Mestinon and prolonged-action neostigmine, 7 have continued to do so. Five patients are taking the prolonged-action Mestinon with regular neostigmine, and two patients are taking prolonged-action Mestinon with ambenonium and regular neostigmine. Seven patients take prolonged-action Mestinon with ambenonium.

Dosage: Patients were transferred from therapy with regular Mestinon bromide by replacing full-strength regular tablets containing doses of 60 mg. each with a 180-mg. prolonged-action tablet. In the case of one-half regular Mestinon tablets, the 90-mg. prolonged-action tablet was substituted. At first the patients were observed for a number of hours, and ergograms were made before and after edrophonium (Tensilon) tests at hourly intervals. It was thus determined and borne out by clinical evaluation that the prolonged-action Mestinon bromide tablets seemed to be effective from two and one-fourth to two and three-fourths times as long as the regular Mestinon tablets. In general, the slow-release Mestinon bromide tablets can be expected to last two and one-half times as long as the ordinary tablets.

The largest dosage of prolonged-action Mestinon bromide prescribed was 6 tablets every six hours for a total of 24 tablets per day, which would be equivalent to 72 ordinary Mestinon tablets. The smallest dosage was one tablet morning and night. The variation in dosage with prolonged-action Mestinon bromide tablets is the same as with regular Mestinon. Increases and decreases in dosage for a patient occurred during the course of treatment. The condition of one patient could be completely controlled, as far as myasthenic symptoms were concerned, by the administration of two prolonged-action Mestinon tablets per day, as compared with identical control of symptoms by the administration of three prolonged-action neostigmine tablets. Once a patient has been adjusted to this form of prolonged medication, changes do not seem to occur in the difference of absorption rates. However, in some patients who were completely controlled on a six-hour basis the interval eventually had to be reduced to four hours.

Apparently there is no difficulty, as far as the age of the patient is concerned, in absorbing the material, and both the severe and the mild cases were equally benefited. We have had no reactions whatsoever from the prolonged-action Mestinon tablets, except that, when the dosage has been too strong, overdosage symptoms have occurred. There is no question that in suitable patients a prolonged-action Mestinon tablet of the type described gives a prolonged medication effect superior to the ordinary tablet and is, therefore, of great benefit to some patients. The duration of the action varies with the severity of the disease, the shortest being 4 hours, the average approximately 6 hours, and the longest 12 hours. Of 109 patients transferred to therapy with prolonged-action tablets of Mestinon bromide, 82 have continued their use and prefer them because of the decreased frequency of medication and smoothness of action (table 2). Thirty-two of the 82 patients have found need to combine the prolonged-action Mestinon tablets with other cholinergic drugs.

TABLE 2.—*Results with Prolonged-Action Mestinon Bromide Tablets in 109 Patients*

Clinic	Max. per Day	Min. per Day	Av. per Day	Better than Reg. Med.	Equal	Not So Good	Over-dosage	Total Patients

Total	24	1	10	82	7	5	10	109

Summary

Prolonged-action or slow-release tablets of neostigmine bromide, containing three regular doses of 15 mg. each, and a half-strength form, containing three doses of 7.5 mg. each, have been tried in the treatment of 85 patients with myasthenia gravis. Prolonged-action or slow-release tablets of Mestinon bromide, containing three regular doses of 60 mg. each, and a half-strength form, containing three doses of 30 mg. each, were tried in treating 109 patients with myasthenia gravis. In the case of the neostigmine bromide tablets, 54 of the 85 patients have found them superior to their regular medication and are still taking them. In the case of the Mestinon bromide tablets, 82 of the 109 patients still continue to take these tablets. The greatest value of this type of medication is in eliminating the need of doses during the sleeping hours.

4 E. 89th St. (28) (Dr. Osserman).

The prolonged-action Mestinon bromide tablets used in this study were supplied through Dr. T. C. Fleming of Hoffmann-La Roche, Inc., Nutley, N. J. The original prolonged-action neostigmine bromide tablets were supplied by A. H. Robins Co., Inc., Richmond, Va., and a subsequent form of this material was supplied by Hoffmann-La Roche, Inc.

The Osteoarthritic Joint.—In 1948 we were surprised to note that the temperature inside the osteoarthritic joint was not normal or slightly subnormal as we had supposed, but rather was increased. The normal knee joint temperature is about 33 degrees C., the active rheumatoid arthritic knee temperature is about 37 degrees C., and the osteoarthritic knee about 35.5 degrees C. An asymptomatic knee, even showing extensive degeneration on x-ray, usually had a normal joint temperature. After weight-bearing exercise the temperature of an osteoarthritic knee rose much more than the normal or rheumatoid arthritic joint, often to 40 degrees or 41 degrees C. Further, the rate of cooling of such a joint on rest after exercise was much slower than in either the normal or rheumatoid joint, often requiring several hours before the control temperature was reached. From these observations we have concluded that a chronic low-grade inflammation or congestion does exist in the symptomatic or active osteoarthritic joint, possibly a result of frequent irritation of the synovium by the excessive heat of friction on use. The slower rate of cooling would also indicate a decrease of blood flow through the membrane. Since the osteoarthritic experiences his joint pain mainly during and after prolonged use, we may have a logical explanation of his pain at last. A marked congestion of the synovium resulting from the excessive heat of friction, with the delayed dispersion of this heat, could account for the stiffness of the joint after periods of rest. More definitive proof is needed, however, before this theory is completely accepted.—J. L. Hollander, M.D., The Diagnosis and Management of Osteoarthritis, *Cincinnati Journal of Medicine,* November, 1956.

FREQUENCY OF DEFECTS IN INFANTS WHOSE MOTHERS HAD RUBELLA DURING PREGNANCY

Morris Greenberg, M.D., Ottavio Pellitteri, M.D.
and
Jerome Barton, B.A., New York

The authors report the results of actual examination of infants born to mothers in whom rubella during pregnancy was diagnosed by a physician. Of 104 women who had rubella during the first trimester, 28 delivered normal infants. Congenital defects were found in 3 infants; there were 3 stillbirths, 12 other fetal deaths, 48 therapeutic abortions, and 10 cases lost from study. The incidence of congenital deformities among the live-born babies of women with rubella during the first trimester of pregnancy was 9.7%. No controls were used, so that a comparison with women who had no rubella could not be made. Rubella appears to increase the likelihood of malformations, but the high rates of incidence set by early authors are exaggerated. The recommendation of therapeutic abortion because of rubella should not become routine, but should take into account all known factors in the situation, such as the age and fertility of the mother. Until more information is obtained on relative risks, physicians owe it to their patients and to society to advise parents to expose their susceptible young daughters to rubella.

The association between rubella in a pregnant woman and the birth of a malformed infant, which was first indicated by Gregg,[1] has been stressed so strongly and advertised so widely that many physicians and pregnant women assume that one is necessarily followed by the other. As a result, therapeutic abortions are advised by physicians and demanded by pregnant women. In New York City, from 1949 to 1955, 45 therapeutic abortions were performed in 104 women who had rubella during the first three months of pregnancy. In 1943 Swan and associates[2] published the results of an investigation of congenitally malformed infants. The investigation was retrospective in design. It started by observing infants with malformations and then questioning their mothers on the occurrence of rubella during their pregnancies. The authors concluded that, if a woman had rubella during the first two months of pregnancy, the chance of giving birth to a congenitally defective child was 100% and, if she contracted rubella during the third month, the chance was about 50%. Numerous case reports soon appeared, and several retrospective studies were initiated. In an investigation conducted by Miller[3] for the American Academy of Pediatrics, out of 132 infants whose mothers had rubella during pregnancy, 86% had congenital defects. Wesselhoeft,[4] in 1949, summarized the reports in the literature, most of them retrospective in nature. Of 780 infants whose mothers had rubella in pregnancy, 656 or 80% were malformed. Such astounding percentages have been accepted by many physicians as authentic rates of incidence, and pregnant women have been urged to have therapeutic abortions performed if they had rubella.

A little thought will show the inaccuracy of the cited percentages. In the retrospective studies cited, the start was made with the defective child, and the path was retraced to discover what happened to the mother during her pregnancy. Frequently the diagnosis of rubella was inaccurate because it was not made by a physician. Often it was unreliable because the mother had to remember an event which occurred a year or more before. The feeling of guilt that possessed a woman for having given birth to a deformed child undoubtedly motivated her sometimes to remember some rash or other eruption that she had early in pregnancy and identify it as rubella. The main objection to this type of study, however, is statistical. No consideration is given to the children who were born normal and who therefore escaped from the study. If 100 pregnant women give birth to 100 infants, of whom 10 are deformed, the incidence is 10%. If the inquiry starts with the 10 deformed infants and works back, the finding will be that all their mothers had rubella during pregnancy. One can thoughtlessly consider this a 100% incidence.

A few prospective studies have been reported. These are summarized by Ingalls and Purshottam,[5] who point out that the criteria for including them were based on certain principles. These were (1) selection of cases before the children's births, (2) diagnosis of rubella by a physician, and (3) record of the outcome of conception. In a paper presented at the annual meeting of the American Public Health Association in 1956, Ingalls added a few more cases from the literature and some from personal reports. He thus obtained a record of 63 births to women who had rubella during the first trimester of pregnancy. Five of these births were stillbirths, and in nine cases there were congenital deformities.

From the Bureau of Preventable Diseases, New York City Department of Health. Mr. Barton is Junior Public Health Intern, New York State Department of Health.

mester, an incidence of 12%. All these studies suffer from the fact that no controls were used. Fox and Bortin's case is included, although there is doubt about the deformity. The infant was cyanotic at birth and is said to have had hydrocephalus at birth "which receded spontaneously, the child being perfectly normal at present."

Comment

The uncommon occurrence of rubella in young adults makes it difficult to collect a large enough series of cases in pregnant women, unless an epidemic of the disease occurs. Thus, in New York City 125 cases of rubella in pregnant women were found in 1955, when there was an epidemic of the disease, whereas only 108 cases were gathered in the six preceding years. To obtain sufficient data, investigation should be undertaken by several groups cooperatively, preferably in communities where rubella is a reportable disease. Such an investigation should start with the pregnant woman with rubella, diagnosed by a physician. Supervision should be continued through pregnancy until term or miscarriage. If a live-born infant results, its condition should be determined; it should be followed for about a year, and an evaluation then made by a physician. Proper controls should be included in order to obtain comparative rates.

From the results of the present study and other reported prospective studies one can conclude that the incidences of congenital malformations reported by early workers are fantastically high and incorrect. The recommendation of therapeutic abortion based on those rates is not medically justified. While an association between rubella early in pregnancy and the occurrence of congenital deformities in the offspring appears to exist, the degree of association has not been determined. Present data indicate a rate of approximately 12% of total births. This is a far cry from rates of 90 to 100% reported in retrospective studies. A controlled prospective study is still needed to obtain comparative rates and to fill other gaps in our knowledge.

It is true that it matters little to the individual woman whether the over-all rate of deformity is great or small if her child is affected. However, there is quite a difference between informing her that she has a 90% chance of giving birth to a normal baby and telling her that there are 90 chances out of 100 that her baby will be deformed. If the woman is young, has a child or two, and does not find it difficult to conceive, she may not want to take the extra risk, even if it is not large. On the other hand, an older primipara, particularly one who has found it difficult to conceive, will be willing to take the risk. At any rate it is scientifically unsound and medically unjustified to state that a risk is higher than the facts warrant.

Until more information is obtained on relative risks, physicians owe it to their patients and to society to advise parents to expose their susceptible young daughters to cases of rubella. This is a mild disease in childhood and rarely causes complications. It confers a permanent immunity and later will obviate the anxiety of pregnant women who may be exposed to it.

Summary and Conclusions

A prospective study of pregnant women with rubella was carried out in New York City from 1949 to 1955. Of 104 women who had rubella during the first trimester of pregnancy, 27% gave birth to normal infants, 3% to congenitally malformed babies, 3% to stillbirths, and 12% to other nonviable fetuses. Therapeutic abortions were performed on 46%, and the cases of 10% were lost from the study.

The incidence of congenital deformities among th live-born babies of women with rubella during th first trimester of pregnancy was 9.7%. In a simila study elsewhere in New York City of pregnant wome who did not have rubella, reported recently, the incidence of congenital malformations was 7%. If onl defects of the brain, eyes, ears, and heart are considered in the latter study, the incidence was 1.9%.

Large-scale prospective studies with controls ar needed to ascertain comparative rates of incidenc The available data indicate a rate of about 12% o total births. The fantastically high rates set by earl authors were based on retrospective studies of malformed infants, which did not account for babies wh were born normal and who therefore escaped from th study, and hence are incorrect. Blanket advocacy o therapeutic abortion in pregnant women who develo rubella during the early months of pregnancy is medically unjustified. Exposure of susceptible young girl to cases of rubella is medically justified and is a soun public-health procedure.

CLINICAL NOTES

HYDRAULIC DEVICE FOR REMOTE CONTROL OF INJECTION DURING CAROTID ANGIOGRAPHY

Joseph A. Epstein, M.D.
and
Bernard S. Epstein, M.D., New Hyde Park, N. Y.

We have long been concerned with the problem of exposure to irradiation in the performance of cerebral angiography. The lead rubber drapes suggested for protection have proved cumbersome in our experience.

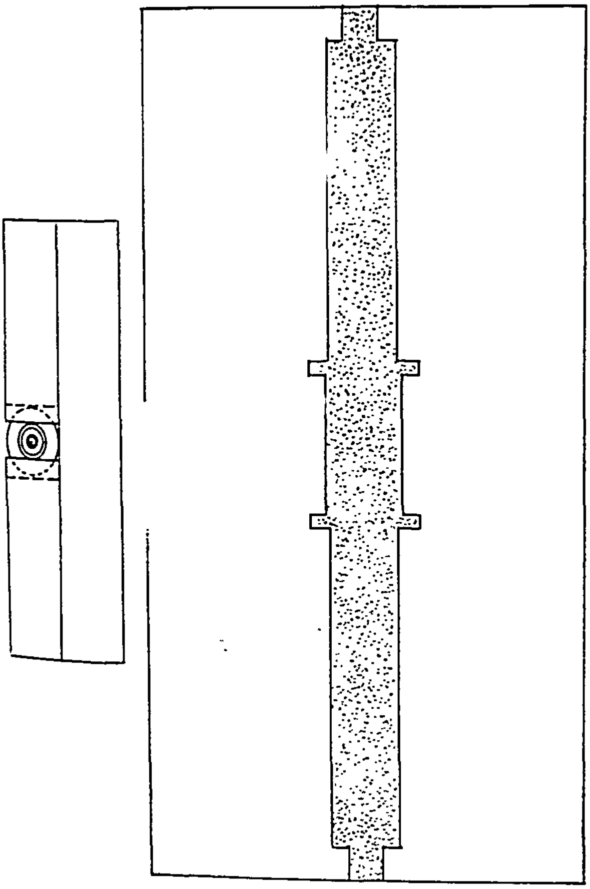

Fig. 1.—Scale drawing of apparatus.

The amount of radiation scatter encountered with careful centering and the use of small cones still is hazardous. Automatic injection devices are limited by the handicap, incurred by losing the desired "feel" of the injection and the expense and complexity of such apparatus.

Up to the present time we have used a combination of careful coning, lead rubber aprons on the operator, and a hasty retreat from the site of the procedure immediately after injecting the contrast medium. This has been fairly successful because the chance of disengaging the Cournand needle is lessened by attaching the syringe to the needle with a 12-in. length of flexible sterile plastic tubing (Venotubes, Abbott Laboratories).

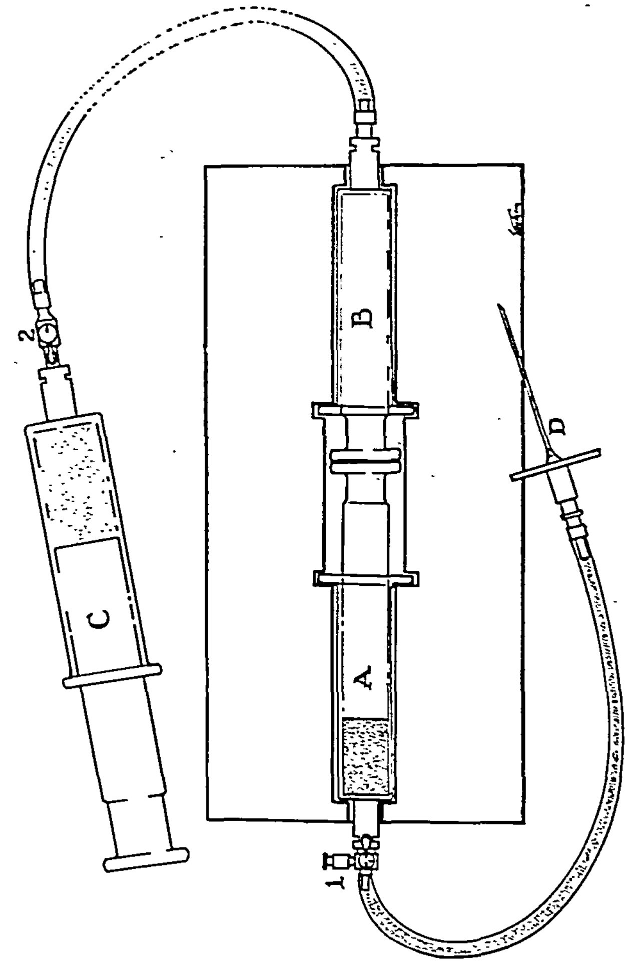

Fig. 2.—Apparatus assembled with syringes in place, ready for use.

From the Department of Surgery, Division of Neurological Surgery, and the Department of Radiology, the Long Island Jewish Hospital.

It occurred to us that a hydraulic device which would retain for the operator the "feel" of the injection and permit the injection to be made from the safe recesses of the control booth would advance our safety. If this were constructed with easily available material at nominal cost, and would work repeatedly and adequately, a contribution worth mentioning might result. We believe that the device described here meets these qualifications.

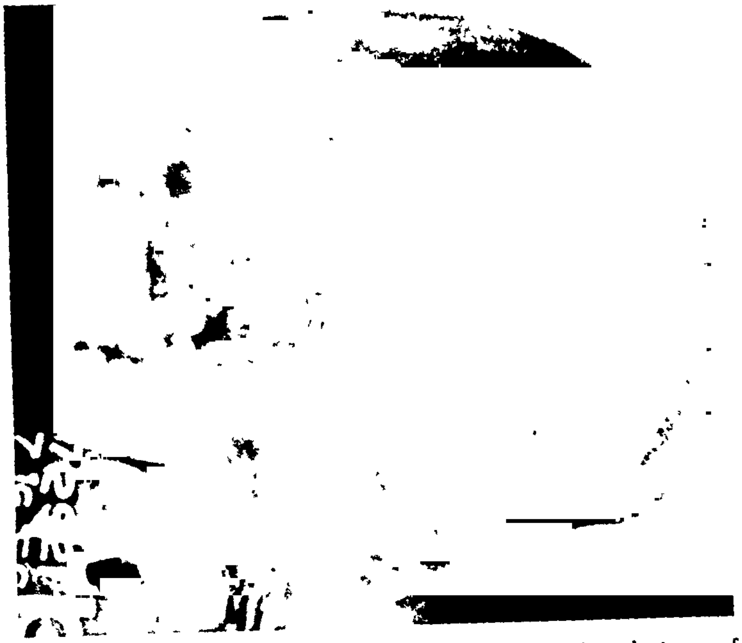

Fig. 3.—Cerebral angiogram using conventional technique of direct injection through short length of plastic tubing. (Cerebral angiogram of same patient made four months later using present apparatus gave same picture.)

The apparatus is constructed from a length of 1-in. soft wood, upon which two additional 1-in. widths are screwed to permit the placement of two 20-cc. Luer-Lok syringes. These are kept in position by cutting out a pair of parallel grooves into which the upper lips of the syringes fit. The distance between these grooves is so set that with one syringe empty and the other containing 8 cc. of contrast medium the heels of both pistons are in apposition (fig. 1). The tip of the syringe containing the contrast medium is connected by means of a short length of sterile plastic tubing to the Cournand needle after this has been successfully introduced and threaded into the common carotid artery. The impeller syringe is connected by means of a 12-ft. length of stiff plastic tubing to a 20-cc. syringe.

This tubing was obtained from a pet shop which carries equipment for aquariums. For hydraulic fluid we use light mineral oil, filling the system so as to include 15 cc. in the actuating 20-cc. syringe. This serves to compensate for any stretch in the plastic hose during the injection (fig. 2).

When the plunger on the 20-cc. master syringe in the operator's hand is pushed forcibly, the fluid enters the impeller syringe, ejecting its piston. This pushes on the piston of the syringe containing the contrast medium, ejecting the contrast medium through the Cournand needle with as much force as if the injection had been made with the syringe immediately attached (fig. 3).

Once assembled, with the tubing wired to the adaptors, the hydraulic system can be kept full constantly. The syringe with the contrast medium can be replaced after each use. This is suggested inasmuch as repeated use of syringes with diatrizoate (Hypaque) or iodopyracet (Diodrast) concentrated is undesirable because of the possibility of the pistons sticking. The entire apparatus is kept in readiness and, after the needle has been introduced, is fixed to the patient's chest by means of a strap encircling the body. Between injections the plastic tube connecting the syringe with contrast medium to the indwelling needle can be clamped off, or an infusion of saline solution may be introduced through a two-way stopcock. If desired, the Cournand needle may be disconnected and a stylet introduced to keep it patent.

We have used this apparatus repeatedly with satisfaction. It provides a safe, reliable, and inexpensive method for the rapid injection of contrast material, enabling the operator to control the procedure from a distance. The apparatus can be used equally well for angiocardiography in infants, and we are constructing a larger one for angiocardiography and aortography in adults.

270-05 76th Ave. (Dr. B. S. Epstein).

Radiochemistry and Atomic Clocks.—Radioactive dating has been one of the radiochemist's principal contributions to geology and cosmology. The formation of lead by the radioactive decay of uranium-238, uranium-235, and thorium-232, in principle, affords a threefold opportunity for the determination of the time elapsed since the most recent crystallization of a mineral. The scale is in terms of thousands of millions of years, the average lifetime of these isotopes. In addition to these three isotopes, two others are of increasing importance—potassium-40, which forms argon-40 in about 10 percent of its disintegrations and has a half-life of 1250 million years; and rubidium-87 which forms strontium-87, again on a time scale of thousands of millions of years. With these five atomic clocks, it is possible to establish the age of the earth with some reliability, and it now appears that the earth and the meteorites probably all are about 5000 million years old. This remarkable result is one of the cornerstones of modern cosmology and geophysics. These atomic clocks are almost entirely contributions of radiochemists. Other possibilities may exist, but radioactive dating is firmly established and is already a cornerstone of geophysics.—W. F. Libby, Radiochemistry, *Scientific Monthly*, September, 1956.

PROLONGED TELEVISION VIEWING AS CAUSE OF VENOUS AND ARTERIAL THROMBOSIS IN LEGS

Meyer Naide, M.D., Philadelphia

It has been recognized that prolonged sitting in one position while driving an automobile for long distances may result in venous thrombosis in the legs. The occurrence of thrombosis of major vessels in the legs of three patients who had been watching television for prolonged periods while sitting in awkward positions drew attention to another cause for the development of thrombophlebitis and arterial occlusion. Television lends itself peculiarly to prolonged sitting during which the legs may not be moved much or at all, since the viewer must face the screen to watch the program, in contrast to listening to the radio where the listener may move about at will. In two of the patients described below venous thrombosis occurred in the legs, with pulmonary embolism. In the third patient thrombosis of the femoral artery occurred as the result of prolonged sitting while the patient was watching television with her legs tucked under her, which was her favorite way of sitting during television programs.

Report of Cases

Case 1.–A 79-year-old physician was seen on Sept. 10, 1956, with a history of pain and swelling of the left leg which had been present for one week. The symptoms had appeared after he had been sitting still for one and one-half hours watching television. The left leg had been in an awkward position with pressure against the popliteal space during this period. Severe pain appeared behind the left knee immediately after the prolonged sitting. When he was seen there was edema of the left leg, and the left calf was 2 cm. greater in circumference than the right. The left popliteal space was very tender and so was the calf. Homans' sign was negative. A diagnosis was made of acute thrombophlebitis of the left leg. He was hospitalized and placed on therapy with heparin and bishydroxycoumarin (Dicumarol). The heparin was withdrawn three days after admission, but therapy with bishydroxycoumarin was maintained. Three days after stopping the heparin therapy, the patient developed sudden pain in the right side of the chest. Two days after the development of chest pain there was x-ray evidence of pleural effusion and thickening, with increased density at the right phrenocardiac angle. The diagnosis was that of a pulmonary infarct. Heparin was given in addition to bishydroxycoumarin with gradual clearing of signs in the chest and subsidence of the symptoms in the legs. He has done well since his discharge in October, 1956, with no postphlebitic symptoms.

Case 2.–A 68-year-old man was seen on Oct. 1, 1956, with a history that he had watched television four weeks previously while sitting with one leg thrown over the side of a sofa chair and had fallen asleep. He awoke about an hour later with discomfort in the right leg and development of swelling and increased pain in the leg the following day. He had been treated with bed rest and penicillin for four weeks before being seen. On examination, the right calf was tender and was 2 cm. greater in circumference than the left. Homans' sign was negative. The right foot was warmer than the left. There was no pallor, cyanosis, or rubor of the extremities. Blood pressure was 140/190 mm. Hg. Rales were heard at both bases. Heart and abdomen appeared normal. A diagnosis was made of thrombophlebitis of the right leg with findings suggestive of pulmonary emboli. He was hospitalized and placed on heparin and bishydroxycoumarin therapy. X-ray of the chest disclosed evidence of pulmonary infarction at the right base. His symptoms subsided gradually with anticoagulant therapy, and he was discharged at the end of three weeks in the hospital with slight residual edema.

Case 3.–A 39-year-old woman came in on April 21, 1952, with a history that on April 15th she had been sitting with the left leg tucked under her off and on for at least two hours while watching television. When the patient stood, the foot then the leg seemed numb, dead, white, and cold. She massaged the leg, but soreness and numbness as well as pallor persisted. She stated that her favorite position while watching television was to have her legs tucked under her. On examination, no pulses were palpable in the left leg, even in the femoral artery. Oscillometric readings were almost zero in the left leg and lower thigh and were normal in the right leg. The left foot and leg were distinctly colder than the right. Color changes on elevating the legs disclosed rapid blanching of the left foot. On dependency the left foot flushed slowly, with final discoloration of the first toe. Blood pressure was 132/184 mm. Hg. Heart, lungs, and abdomen appeared normal. This patient's condition gradually improved with vasodilator drugs, although she still has intermittent claudication on walking about a block and a half. The left femoral pulse is still absent.

Comment

While watching television programs a viewer may sit for hours at a time in a relatively static position, perhaps moving only occasionally. Homans [1] has emphasized the frequency of thrombosis of the deep leg veins as the result of prolonged sitting, particularly in automobiles. Tall men are peculiarly susceptible to venous thrombosis after long automobile trips.[2] Simpson [3] reported 21 sudden deaths from pulmonary embolism in persons in or leaving air-raid shelters in World War II. The cause was found to be venous thrombosis in legs, resulting from long periods of sitting on chairs or benches with the edges compressing the veins. Wright [4] has pointed out the importance of moving frequently and removing girdles and other clothing that bind in the fold of the groin during travel that requires prolonged sitting.

From the Department of Medicine, Woman's Medical College of Pennsylvania, and the Department of Medicine, Albert Einstein Medical Center.

One need not belabor the point that stasis is a contributory factor in the development of venous thrombosis. Television viewing, which requires that the individual face the screen for long periods, may create a favorable situation for the development of thrombosis of veins and also of arteries, particularly if the legs are not moved frequently or if there is compression of the popliteal vein as the result of awkward sitting with pressure on the poplilteal space. Television viewers should get up and move about at least once an hour in addition to moving the legs frequently. Girdles and other tight garments should be removed before prolonged television viewing. It is of possible significance that the two patients who developed venous thrombosis were elderly.

Summary

Three patients developed major thrombosis in the legs, two in the veins, with pulmonary embolism, and one in the femoral artery, following prolonged sitting in awkward positions while viewing television programs. Prolonged television viewing without moving the legs, particularly by elderly individuals, may cause sufficient stasis to produce venous and arterial thrombosis. Television viewers should get up and move about at least once an hour in addition to moving the legs frequently. Girdles and other tight garments should be removed before prolonged television viewing.

IMPLANTATION METASTASIS AFTER NEEDLE BIOPSY OF LIVER TUMOR

Samuel Zelman, M.D., Topeka, Kan.

Implantation of tumor cells in the track of a needle biopsy of the liver apparently occurs rarely. It was observed in one reported instance after needle aspiration of a malignant hepatoma.[1] Another instance involving hepatoma was mentioned in a discussion.[2] It has not been encountered in Schiff's extensive experience.[3] The case reported below is the only such in an experience which included 41 aspirated malignant tumors, 34 of them from the liver.

Report of a Case

A 59-year-old male had an abdominoperineal resection of an adenocarcinoma of the rectum in July, 1955, and was observed regularly thereafter for recurrence. Beginning in December, 1955, he had indigestion, gradual weight loss, liver enlargement, and a gradually rising serum alkaline phosphatase level. Needle aspiration biopsy of the liver through an anterior approach in July, 1956, revealed metastatic adenocarcinoma. In December, 1956, a metastatic nodule was found in the abdominal skin at the site of needle entry. When surgically excised, this nodule measured 1 cm. in diameter and was accompanied by a second smaller nodule found directly beneath it subfascially. On histological examination, both nodules were found to consist of adenocarcinoma. The patient died in January, 1957, when extensive metastases were found at autopsy.

Comment

This is the third known instance of implantation metastasis after aspiration of liver tumor and the first involving metastatic liver tumor. The rarity of such an occurrence, as well as the generally hopeless prognosis of malignant tumors in the liver, should relieve concern regarding the possible implantation of metastases along the track of needle biopsy of the liver.

Dr. Phyllis J. Burdon of the Medical Service gave permission to report the case.

SPECIAL ARTICLE

SOCIAL SECURITY FOR PHYSICIANS

1. THE OLD AGE, SURVIVORS AND DISABILITY INSURANCE PROGRAM (OASDI)

The United States Social Security Act, passed in 1935, contains several different programs under the general heading of "Social Security." We are concerned here only with that portion of the act originally known as the Federal Old Age Benefit System, later the Old Age and Survivors Insurance program, and now, after many amendments, the Old Age, Survivors and Disability Insurance Program. The original objective sought was twofold in character: (1) to remove older workers from the labor force and (2) to provide a federal basic minimum retirement benefit to such workers.

The act originally contemplated and provided for a close relationship between the amount of Social Security taxes paid and the benefits received by retired workers. The plan was relatively simple. Only retired workers over 65 were to receive benefits. A contributory system was established based on special taxes paid by workers and employers. The proceeds were invested in government securities which were maintained in a special fund.

Since 1935 the program has been changed in many fundamental respects:

1. Coverage has been broadened so that substantially the entire working population is now covered, plus their dependents and survivors. Only self-employed physicians, certain government employees, and a few other small groups are excluded.
2. Existing benefits have been increased, new benefits and beneficiaries added, and Social Security tax schedules changed. The original objective of income maintenance for retired workers, later for their survivors and dependents, was broadened significantly in 1954 and 1956 when special income maintenance provisions were included for the disabled.

In broad outline the act, as presently constituted, includes the following provisions which are of particular interest to self-employed physicians.

Social Security Taxes

The self-employed pay Social Security taxes annually on the first $4,200 of income. The tax is paid at the time of filing the individual income tax return. It is paid regardless of age and whether or not the individual is receiving Social Security benefits.

The following table shows current Social Security tax rates and presently scheduled increases for the self-employed:

Year	%	Tax (%×$4,200)
1957-1959	$3\frac{3}{8}$	$141.75
1960-1964	$4\frac{1}{8}$	173.25
1965-1969	$4\frac{7}{8}$	204.75
1970-1974	$5\frac{5}{8}$	236.25
1975-	$6\frac{3}{8}$	267.75

The taxes computed in this table will, of course, be appreciably higher if the tax rate or the base earnings taxed are increased by any future Congress. Several bills now in Congress include increased taxes and higher base earnings subject to tax.

Eligibility for Benefits

Old Age Retirement Benefit.—You are eligible for retirement benefits at age 65 if you are (*a*) "fully insured," (*b*) have retired, and (*c*) have applied for payments. You are "fully insured" at retirement age if you have a "quarter of coverage" for each two calendar quarters after 1950. A "quarter of coverage" corresponds to a calendar quarter, and is considered a "covered" quarter if self-employed earnings during that year are at least $400. To reach "fully insured" status one must have at least six quarters of coverage. The attainment of 40 quarters of coverage entitles one to a "fully insured" status for life. A 1954 provision with respect to disability permits a covered worker to omit quarters during which his earnings record was "frozen" due to disability.

Eligibility for a retirement benefit also requires satisfaction of a work test. Between ages 65 and 72 you may not earn more than $1,200 in a year and receive benefit payments for all 12 months of the year (at age 72 the work test provision does not apply). In general one month's benefit is lost for each $80 or fraction thereof of earnings over $1,200 in a year. However, the monthly benefit may be paid no matter how much the $1,200 maximum is exceeded for any month in which the self-employed person does not render "substantial services in self-employment." The Social Security Administration has defined "substantial services" as actively engaging in the operation of one's trade or business. Decisions are made on the facts in each case. Income from savings, investments, pensions, and insurance is not included under these provisions.

The present maximum monthly benefit payable to the retired worker is $108.50.

Retirement Payments to the Self-employed Worker's Wife.—The wife of a retired "fully insured" worker is eligible for retirement payments if she is age 62 or over, or has a dependent child who is under 18 or disabled. The wife at 65 receives one-half of the monthly payment to the self-employed retired worker. The applicable amount, for example, for a 65-year-old wife whose husband was receiving maximum retirement benefits would be $54.30; the total for the couple would be $162.80. Similarly, a wife of a retired self-employed worker receiving maximum benefits who had a dependent child under 18 or disabled would receive the same amount ($54.30 monthly) regardless of her age. A retired worker's wife between ages 62 and 65 receives a reduced benefit. A wife below the age of 62 without a dependent child under the age of 18 or disabled child receives no benefit.

Survivors' Benefits.—Monthly payments are made to a widow age 62 or over of a self-employed worker who was "fully insured" at death. Such a widow receives a maximum benefit of $81.40. A widow of any age (or a dependent divorced wife) with a dependent child under 18 or disabled of a self-employed worker who at death was covered under the act (not necessarily "fully" insured) is also eligible for a survivor payment. The maximum amount for a widow with one child is $162.80 and for a widow with two children, $200. Payments cease when the children reach 18. The widow again receives a benefit when she reaches 62.

Lump Sum Payment at Death.—The widow of a self-employed covered worker receives a maximum lump sum death payment of $255 for burial expenses.

Disability Benefits.—A self-employed worker at age 50 adjudged to be disabled as defined in the law who is "fully insured" and who has been covered for at least 20 quarters in the 40 calendar quarters before the onset of the disability is eligible to receive the retirement benefit that he would have received if he had reached the age of 65 ($108.50 maximum). No retirement benefit is provided for wives or dependent children under the existing program.

Disability under the act is defined as "any medically determinable physical or mental impairment which can be expected to be either of indefinite duration or result in death, and which renders an individual unable to engage in any substantial gainful activity."

Constitutionality

In 1937 the constitutionality of the Federal Old Age Benefit program was argued before the Supreme Court. In general the affirmative decision of the act's constitutionality was based on the argument by the government that this program was not "insurance" but a public welfare program based on taxation and the payment of benefits by the government on a statutory and noncontractual basis. The Supreme Court construed the program to be within the spirit of the general welfare clause of the Constitution on the basis of this argument. Notwithstanding the clear position of the Court that the Federal Old Age Benefit program was not insurance, Congress in 1939 changed the name of the program from Federal Old Age Benefit to Old Age and Survivors Insurance. The word "insurance" has been used routinely since that time to describe the program.

Social Security Trust Fund

Social Security taxes cannot by law be earmarked. All taxes are transmitted to the Treasury of the United States Government. The fund however is credited by the Treasury with receipts equivalent to the Social Security taxes received. The fiscal procedure is for the Treasury to transmit to the fund special bonds designated as "public debt obligations for purchase by the Trust Fund." Interest on these public debt obligations is applied in the same way. The fund represents the surplus of Social Security taxes over the benefits paid out plus the accrued interest less administrative expenses. Its value is represented by the special bonds issued by the Treasury which become a part of the public debt.

The Social Security taxes, plus the accrued interest, projected through 1975 are designed to insure revenues adequate to meet the obligations to eligible beneficiaries. In years when Social Security tax revenues are less than that year's benefit payments the trustees of the reserve fund exchange the special non-negotiable bonds for negotiable bonds from the United States Treasury and sell those bonds on the open market. No attempt is made to build up a reserve fund actuarially equal to the total projected obligation now estimated at approximately 250 billion dollars.

The principal purpose of the reserve fund as it was established in 1935 is to insure the continuation of contributory, special taxes from workers and employers, the proceeds of which, together with accrued interest, are designed to underwrite the total cost of the program. It is the contention of the proponents of the reserve fund mechansim that the contributory system could not have been established without a reserve fund identified as such, into which excess tax payments were placed as earmarked special bonds. The reserve fund is said to insure that the general revenues of the government will never be used to pay Social Security benefits. In 1950, to underscore this objective of the reserve fund the Congress voted that general revenue shall not be used in this program.

Many students of Social Security and government fiscal management contend that the reserve fund is a fiction that serves no useful purpose. They contend that the fund consists only of earmarked government obligations and that the interest applied to the account is in effect a double taxation on the people. They point to the repeated evidence of misunderstanding concerning the nature of the fund as shown by congressional attempts to add new expensive programs based on the false notion that idle cash is available in the fund. Furthermore, these opponents contend the fund promotes the fiction of absolute "rights" to benefits based on part ownership of the fund. The beneficiaries of the fund in a true sense, they say, are anonymous and current taxpayers have no statutory or other right to any portion of the bonds in the trust fund.

Given a Social Security program, it can be said that a reserve fund provides certain practical administrative advantages but at the same time promotes dangerously false concepts of the nature of the program.

Future Program

This Congress will consider numerous amendments to OASDI which increase benefits and taxes, and introduce fundamentally new concepts. To the medical profession the most important are those which for the first time authorize hospital or medical care in addition to cash benefits. A specific proposal that will undoubtedly receive wide support is the reimbursement of hospitals by the fund for hospitalization of eligible retired Social Security beneficiaries. It is also being proposed that the present cash payment to eligible disabled beneficiaries at age 50 be made regardless of age and—of special interest to medicine—that rehabilitation of the disabled person be financed through OASDI funds.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

The Registry, established under the direction of the Subcommittee on Blood Dyscrasias of the Committee on Research, has received 257 case reports from 74 cooperating physicians in which a dyscrasia was suspected as having been caused by drugs or chemical substances. A review of these reports reveals that 10 cases were apparently associated with the use of the new drug promazine hydrochloride. Since the Registry is intended as a system for the alerting of physicians, it was concluded that the possible association of these cases with the use of this drug was sufficiently suggestive to warrant bringing this fact to the attention of the medical profession.

Norman De Nosaquo, M.D., *Secretary,*
Committee on Research.

BLOOD DYSCRASIAS ASSOCIATED WITH PROMAZINE HYDROCHLORIDE THERAPY

A review of the reports received by the Registry since July, 1956, revealed 10 cases of blood dyscrasias apparently associated with promazine (Sparine) hydrochloride therapy. A search of the English-language medical literature to the date of the preparation of this statement has uncovered two case reports of granulocytopenia associated with promazine hydrochloride therapy, one of which is among those reported to the Registry. Wyeth Laboratories has been most cooperative and has supplied an additional record of 8 cases not previously reported to the Registry, bringing the total to 18 cases in which promazine therapy was suspected as being associated with a case of blood dyscrasia. It should be pointed out that in seven instances the patients received other drugs such as chlorpromazine (Thorazine) hydrochloride. Although all of the cases of blood dyscrasias associated with the use of promazine hydrochloride probably have not been reported, it has been suggested that the rate of incidence of a dyscrasia is relatively low.

Although depression of granulocytes was prominent in every case reported, the bone marrow studies in some cases indicated a depression of other cellular elements as well. Of the 18 known cases, we have information that 4 ended fatally. In cases that were identified early, cessation of use of the drug and institution of appropriate measures were usually followed by fairly prompt recovery. Physicians who prescribe promazine hydrochloride should instruct attendants, nurses, and patients to discontinue use of the drug and to report immediately if there is any sudden occurrence of symptoms such as sore throat, fever, or malaise. These instructions must be stressed. The interim blood cell counts alone cannot be relied upon because the condition could develop suddenly between routine examinations.

Wyeth Laboratories has included a forceful warning and has placed it prominently in the leaflet available to the medical profession. The firm should be commended for its diligence and willingness to cooperate with the subcommittee in its effort to bring this matter to the attention of physicians. Since the drug may possess potential for some harm, the subcommittee suggests that physicians limit its use to those conditions in which such use is warranted and avoid its use in the treatment of trivial or minor complaints.

Report to the Council

The Council has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

The following recommendations on first-aid measures for poisoning have been adopted by the Committee on Toxicology. These recommendations are made in response to numerous requests to the American Medical Association for general instructions for poisoning emergencies. They are intended for use in educating the public in what to do when poisoning occurs.

Bernard E. Conley, Ph.D., *Secretary,*
Committee on Toxicology.

RECOMMENDATIONS OF COMMITTEE ON TOXICOLOGY ON FIRST-AID MEASURES FOR POISONING

Emergency Telephone Numbers:
PHYSICIAN ....FIRE DEPT. ....
HOSPITAL .... (resuscitator)
PHARMACIST ....POLICE ....
RESCUE SQUADS ....

The aim of first-aid measures is to help prevent absorption of the poison. SPEED is essential. First-aid measures must be started at once. If possible, one person should begin treatment while another calls a physician. When this is not possible, the nature of the poison will determine whether to call a physician first or begin first-aid measures and then notify a physician. Save the poison container and material itself if any remains. If the poison is not known, save a sample of the vomitus.

Measures To Be Taken Before Arrival of Physician

I. *Swallowed Poisons*

Many products used in and around the home, although not labeled "Poison," may be dangerous if taken internally. For example, some medications which are beneficial when used correctly may endanger life if used improperly or in excessive amounts.

In all cases, *except those indicated below,* REMOVE POISON FROM PATIENT'S STOMACH IMMEDIATELY by inducing vomiting. This can not be overemphasized, for it is the essence of the treatment and is often a lifesaving procedure. Prevent chilling by wrapping patient in blankets if necessary. Do not give alcohol in any form.

A. *Do Not Induce Vomiting If:*
   1. Patient is in coma or unconscious.
   2. Patient is in convulsions.
   3. Patient has swallowed petroleum products (i. e., kerosene, gasoline, lighter fluid).
   4. Patient has swallowed a corrosive poison (symptoms: severe pain, burning sensation in mouth and throat, vomiting).
      CALL PHYSICIAN IMMEDIATELY
      (a) Acid and acid-like corrosives: sodium acid sulfate (toilet bowl cleaners), acetic acid (glacial), sulfuric acid, nitric acid, oxalic acid, hydrofluoric acid (rust removers), iodine, silver nitrate (styptic pencil).
      (b) Alkali corrosives: sodium hydroxide—lye (drain cleaners), sodium carbonate (washing soda), ammonia water, sodium hypochlorite (household bleach).

If the patient can swallow after ingesting a *corrosive poison,* the following substances (and amounts) may be given:

For acids: milk, water, or milk of magnesia (1 tablespoon to 1 cup of water).
For alkalis: milk, water, any fruit juice, or vinegar.
For patient 1-5 years old—1 to 2 cups.
For patient 5 years and older—up to 1 quart.

B. Induce Vomiting When Non-corrosive Substances Have Been Swallowed:
   1. Give milk or water (for patient 1-5 years old—1 to 2 cups; for patient over 5 years—up to 1 quart).

   2. Induce vomiting by placing the blunt end of a spoon or your finger at the back of the patient's throat, or by use of this emetic—2 tablespoons of salt in a glass of warm water.

When retching and vomiting begin, place patient face down with head lower than hips. This prevents vomitus from entering the lungs and causing further damage.

II. *Inhaled Poisons*
   1. Carry patient (do not let him walk) to fresh air immediately.
   2. Open all doors and windows.
   3. Loosen all tight clothing.
   4. Apply artificial respiration if breathing has stopped or is irregular.
   5. Prevent chilling (wrap patient in blankets).
   6. Keep patient as quiet as possible.
   7. If patient is convulsing, keep him in bed in a semidark room; avoid jarring or noise.
   8. Do not give alcohol in any form.

III. *Skin Contamination*
   1. Drench skin with water (shower, hose, faucet).
   2. Apply stream of water on skin while removing clothing.
   3. Cleanse skin thoroughly with water; rapidity in washing is most important in reducing extent of injury.

IV. *Eye Contamination*
   1. Hold eyelids open, wash eyes with gentle stream of running water *immediately*. Delay of few seconds greatly increases extent of injury.
   2. Continue washing until physician arrives.
   3. *Do not use chemicals*; they may increase extent of injury.

V. *Injected Poisons* (scorpion and snake bites):
   1. Make patient lie down as soon as possible.
   2. Do not give alcohol in any form.
   3. Apply tourniquet above injection site (e. g., between arm or leg and heart). The pulse in vessels below the tourniquet should not disappear, nor should the tourniquet produce a throbbing sensation. Tourniquet should be loosened for 1 minute every 15 minutes.
   4. Apply ice-pack to the site of the bite.
   5. Carry patient to physician or hospital; DO NOT LET HIM WALK.

VI. *Chemical Burns*
   1. Wash with large quantities of running water (except those caused by phosphorus).
   2. Immediately cover with loosely applied clean cloth.
   3. Avoid use of ointments, greases, powders, and other drugs in first-aid treatment of burns.
   4. Treat shock by keeping patient flat, keeping him warm, and reassuring him until arrival of physician.

Measures to Prevent Poisoning Accidents

A. Keep all drugs, poisonous substances, and household chemicals out of the reach of children.
B. Do not store nonedible products on shelves used for storing food.
C. Keep all poisonous substances in their original containers; do not transfer to unlabeled containers.
D. When medicines are discarded, destroy them. Do not throw them where they might be reached by children or pets.
E. When giving flavored and/or brightly colored medicine to children, *always* refer to it as medicine—*never* as candy.
F. Do not take or give medicine in the dark.
G. *READ LABELS* before using chemical products.

CHEMICAL LABORATORY

The Chemical Laboratory has authorized publication of the following statement.

Walter Wolman, Ph.D., *Director.*

Monographs of tests and assays for new and nonofficial drugs adopted by the Chemical Laboratory of the American Medical Association represent an expression of opinion as to what might constitute adequate tests and assays to serve as a reference guide to those interested in the identity and quality of a new and nonofficial drug.

Completed monographs are published in the journal *Drug Standards* for those interested in the details of the procedures. Monographs on the following drugs have appeared in the July-August, 1957, issue of that journal. The cooperation of the listed pharmaceutical firms that furnished samples and data is acknowledged.

Cyclizine	(Burroughs Wellcome & Co., Inc.)
Cyclizine hydrochloride	(Burroughs Wellcome & Co., Inc.)
Cyclizine lactate	(Burroughs Wellcome & Co., Inc.)
Meclizine hydrochloride	(Pfizer Laboratories)
Mephentermine	(Wyeth Laboratories)
Nylidrin hydrochloride	(Arlington-Funk Laboratories)

be answered by unanimous agreement of all health groups rather than incidental opinions, and it is up to local medical leaders to coordinate such information before, not after, announcement is made to the public.

The second Special Committee on Influenza report attempts to prevent duplication of health efforts, as well as to prevent conflicting information from reaching the public. In disseminating health information, experience has proved that successful results are more easily achieved when the audience respects the reliability of the source. Integrated knowledge can not only prevent confusion but, moreover, can reduce morbidity.

THE PHILADELPHIA MEETING

The forthcoming meeting of the American Medical Association in Philadelphia will provide an opportunity for all members to learn first hand what their Association is doing on their behalf. It also offers an opportunity for others to observe how the medical profession through organized efforts is serving the public. Reports covering all phases of Association activity will be presented to the House of Delegates, and any member is welcome to attend the meetings of the House. In fact, all members are urged to attend.

Philadelphia as a convention city has much to offer. For those interested in sightseeing, for those with an interest in medical schools and hospitals, and for those with an eye for history, this city is well known. But, in addition, there will be today's modern medical concepts as revealed by leaders in all branches of medical life. And also there will be the occasion to review what the American Medical Association has done during 1957 and what are some of its plans for the future.

Time and time again people are heard to criticize something of which they have little personal knowledge. Or they are heard to complain about an action taken by their medical society but on questioning admit they have made no attempt to express their views to the society. The purpose of organizing into societies is to permit an exchange of ideas and to encourage cooperatively that which is good. All physicians should be members of their county, state, and national medical associations to share and benefit from a program for the exchanging of ideas. And they should not hesitate to express their views no matter how divergent they may seem to be. The views may not be in accordance with the expressed wishes of the majority, but at least they will have been aired and shared. But if a dissenting doctor does not even attend the meetings of his society, he cannot expect to exert an influential voice. Nor should his views be expected to weigh heavily with others if he seems to be so little interested in his colleagues that he does not wish to associate with them at medical meetings.

There are so many problems confronting medicine today that any meeting is certain to provide discussion on some topic of interest for all members of the profession regardless of their field of activity. Medical education, retirement plans, malpractice, medical care for the public and for the armed forces, civil defense crises, new treatments and diagnostic measures, visual aids, corporate practice of medicine, medical ethics, and other subjects too numerous to mention are discussed and discussed again and again at medical meetings. And they are now a part of the everyday life of the doctor, whether he be practitioner, administrator, teacher, or researcher, as they have never been previously. The doctor as an individual must be informed on what is new for him and his patient. And for his own good and for his patients' welfare he must know what problems are facing his profession as a whole. With such information he can better meet his obligations. Without it he may find himself in some embarrassing situations from time to time. The Philadelphia meeting is designed to focus attention on such areas of interest and to permit the Association as an organization to report to its members. Now it is up to the members to learn first hand some of the things they are receiving for their dues.

SOCIAL SECURITY FOR PHYSICIANS

The House of Delegates of the American Medical Association at the June, 1957, meeting reaffirmed its long-standing opposition to the compulsory coverage of physicians under the Old Age and Survivors Insurance provisions of the Social Security Act. The House also recommended a stepped-up informational program which would explain to every Association member the reasons underlying the policy on this issue.

To help carry out that directive, THE JOURNAL this week begins publication of a series of three articles on "Social Security for Physicians," which will be appearing in the Special Article section. This week's article, "The Old Age, Survivors and Disability Insurance Program (OASDI)," is on page 683. Part 2 of the series, entitled "Position of the Medical Profession Concerning the Coverage of Physicians Under the Social Security Act," will be in the October 19 issue. The October 26 issue will carry part 3, called "Survivorship Benefits—the Bait."

Although there are differences of opinion within the profession on this question, all evidence to date indicates that a majority of physicians agree with the Association's policy. However, during the past year or so the picture has been somewhat confused by the vigorous drum-beating efforts of the leftist Physicians Forum. It is hoped, therefore, that this series of articles—and subsequent material to be published by THE JOURNAL—will help clarify the issue and enable physicians to reach a clear-cut decision based on facts rather than propaganda.

SPECIAL COMMITTEE ON INFLUENZA

ASIAN INFLUENZA—A SPECIAL REPORT TO MEDICAL SOCIETIES

The following report, prepared by a subcommittee consisting of Drs. Charles W. Steele, Chairman, Lewiston, Maine; David Henry Poer, Atlanta, Ga.; and Roscoe L. Sensenich, South Bend, is presented for the guidance of the medical profession by the A. M. A. Special Committee on Influenza and has been authorized for publication in THE JOURNAL.

FRANK W. BARTON, *Secretary.*

The success of any program designed to minimize the medical and health problems arising from an Asian influenza epidemic, should it materialize, will depend on the leadership and extent of participation of the medical profession. The public looks to the medical profession for this leadership in these emergency situations and American medicine wants a sound medical plan and an effective organization to meet the medical aspects of any epidemic. Experience has shown the infecting virus of Asian influenza to be highly contagious, accompanied by a rapid onset and high incidence or attack rate. For these reasons, the A. M. A. Special Committee on Influenza points to the fact that the ability of the medical profession to discharge its responsibilities in the event of an epidemic of this nature will depend largely on how promptly they have taken steps to plan ahead.

To assist medical societies in organizing the health resources of the community to meet the emergency requirements of an Asian influenza epidemic, the Committee feels that a review of some of the factors to be considered, together with suggested operational guides, might be helpful. In considering the problem in broad terms, the twofold objective of this report is (1) to assist in the formulation of medical and health plans that can be put into operation in the event an epidemic occurs and (2) to assist state and local medical societies in cooperation with official health agencies to plan a program that will achieve the highest level of vaccination possible, in accord with local priority plans, with the amount of vaccine available.

Many of the state and county medical societies have already prepared excellent plans and are otherwise actively engaged with preparedness programs. The Committee suggests that an exchange of programs and plans among states, as well as between constituent medical societies, might be of practical value in the coordination of activities, as well as in uniformity of action in special phases of the program.

For the past two months, special articles have been published in THE JOURNAL on Asian influenza, and these articles will be continued. Promotional materials and guides are available through the U. S. Public Health Service to assist state and community groups in developing vaccination programs and operational plans.

Because the local health department is the link between the private physician and the state-federal-international reporting system, it is essential that this communication be immediate in order to provide rapid epidemiologic investigation, including laboratory confirmation, where influenza of any type is the tentative diagnosis. Equally as important as the supplying of information to the local health officer is the reciprocal opportunity of receiving up-to-the-minute data from the epidemic intelligence service, which is part of the public health make-up. All public health officials receive regular reports from state and federal sources, and these reports include the locations of individual cases, outbreaks, and most important the exact diagnosis, if and whenever confirmed. A unique part of this service is the notifying of local health officials whenever persons, usually returning from overseas and known to have been exposed to Asian influenza, are returning to their community.

The Committee recommends that each state, county, and local medical society give consideration to:

1. The formation of plans for complete mobilization of all health resources at community level to cope with the impact of influenza epidemics on normal professional services and health facilities. In general, it will be an augmentation of existing services to meet the anticipated epidemic.

2. An estimate of anticipated morbidity, duration of the epidemic, and number of persons ill at the same time, using available experiences and indexes.

3. A forecast of the number of patients that could be treated at home and those requiring hospitalization.

4. A plan for expanded professional care through the utilization of all medical personnel, regardless of type of practice. Action to make full use of hospi-

---

The Special Committee on Influenza consists of Drs. Harold C. Lueth, Chairman, James Z. Appel, Cortez F. Enloe Jr., Carroll P. Hungate, Hugh H. Hussey Jr., Max L. Lichter, David Henry Poer, Roscoe L. Sensenich, and Charles W. Steele.

tal facilities, likewise, should be explored, such as curtailment of elective surgery, diagnostic studies, etc.

5. A determination of effective mobilization plans through the use of surveys of hospital resources, physicians, nurses, and other allied medical personnel, and other means.

6. An assurance of the full utilization of other community services and facilities, such as home nursing care, homemakers service, first aid and care to the sick, to supplement the care needed for all persons in the home and to relieve the demand on hospitals.

7. The possible use of FCDA emergency supplies and equipment and other civil defense planning.

8. A system for the dissemination of epidemiologic information to local physicians available from the Public Health Service on the total national situation and also on a state-by-state basis. A program of epidemic reports by counties to the state and, in turn, reports to the Public Health Service that could be made available to physicians would be ideal.

9. A means for the utilization of a diagnostic laboratory system for the collection of specimens of nose and throat washings and blood samplings to establish the epidemiology of the disease. Technical information on securing, preparing, and forwarding of specimens to the laboratory should be disseminated through state health department channels to insure reliable tests and uniformity of laboratory data that would indicate the presence or spread of the disease. This phase of the program is of tremendous value early in an epidemic. Once an epidemic has started, further laboratory tests are no longer essential.

10. The closest coordination of state and local medical programs with public health agencies and state and local health officials is of utmost importance. There should also be effective cooperation between the health and medical groups and all other related community activity.

11. The admission to hospitals of those persons with influenza with complications or those that constitute a special medical problem or risk. The Committee feels that maximum reliance should be placed upon home care of uncomplicated influenza cases.

12. An informational and educational program to acquaint the public with factual information as to what to do and what to expect. The public should be reassured that there is no cause for alarm concerning an influenza outbreak in view of the fact the illness is of short duration, it is generally mild and with few complications, and it has a very low mortality rate. Emphasis should be made concerning the close cooperation among national, state, and local health and medical groups in the formulation and operational plans to cope with the problem.

Local groups working together can evolve an effective action program, operationally and informationally. The Committee feels that the possible magnitude of the problem warrants serious attention of local medical societies well in advance of any epidemic outbreak. Too little or too late could be disastrous, even though it is recognized that some portions of the program may never be used. Local medical societies must give the type of leadership in this matter that the public expects. Even if the Asian influenza epidemic should never strike, the public and the profession would gain by this type of organization: first, in health education; second, in drawing people in the health groups together to form an effective action group which could meet special emergency health problems; and, third, it could serve as an actual working experience in medical disaster situations, due to either natural or war conditions.

Realizing that some misunderstanding has probably resulted in the widespread dissemination of information with reference to the vaccine program, the Committee takes this opportunity to briefly review the achievements in the manufacture, production, and distribution of Asian influenza vaccine.

The progress which has been made in the development of a vaccine containing the Asian strain has been significant and noteworthy, if not phenomenal. The first strains were provided to the manufacturers on May 22; the first vaccine was released for general use on Aug. 12, and each succeeding week since that date increasing lots of the vaccine have become steadily available. It is anticipated that some time in October a maximum weekly production rate of 5 to 7 million cubic centimeters will be reached by the six manufacturers who have been licensed to produce the vaccine.

According to Public Health Service reports, a production goal of 85 million cubic centimeters by January, 1958, is the present estimate of supply potential. As of Oct. 1, a total of 13,502,947 cubic centimeters of the vaccine had been released for civilian and military use. Of this amount, the military departments received 4,015,700 cubic centimeters, and it is anticipated that by the end of October most of the members of the armed forces will have received the first of two scheduled inoculations. The remaining 9,487,247 cubic centimeters has been released through the usual commercial drug channels for civilian use. When maximum production goals are reached in October, it is estimated that approximately 20 million cubic centimeters or more per month will be available for distribution.

A polyvalent preparation containing an Asian and other strains of virus, no doubt, would be the ideal vaccine; however, the monovalent Asian strain virus has been accepted in order to facilitate production and to provide as large a volume as possible for immunization. Present requirements call for an antigenic virus mass of 200 CCA (chick-cell-egg agglutination) units per cubic centimeter. Past experience, according to the Public Health Service, has indicated that a single injection of influenza vaccine is about 70% effective. The actual effectiveness of the Asian influenza vaccine cannot, of course, be established as yet. Protection develops in 10 to 14 days and lasts approximately one year.

The Public Health Service has undertaken a vigorous campaign to urge maximum public use of the vaccine just as rapidly as supplies become available. Dr. Leroy E. Burney, Surgeon General, U. S. Public Health Service, noted, "there will not be enough time, of course, to produce and administer sufficient vaccine to immunize a majority of the population before the influenza season. However, the vaccine is the only known preventive and we want to make the best use of it we can."

The Public Health Service, in cooperation with the American Medical Association, is encouraging a nationwide voluntary program of vaccination against the prevalent strain of influenza. The Public Health Service will not request federal funds for the purchase or administration of the vaccine, except for its own legal beneficiaries. Community resources, both public and private, should be encouraged to provide for persons who are unable to pay for such protection.

At the suggestion of the Public Health Service, a voluntary interstate allocation system for the distribution of the vaccine has been worked out by the manufacturers to assure an equitable availability of vaccine supplies throughout all parts of the country. The voluntary system is patterned along the following lines:

1. Each state would be entitled to shipments of a percentage of vaccine produced by each manufacturer equal to the percentage which that state's population bears to the total population of the United States.
2. Out of each week's vaccine production, manufacturers would establish for each state a quota of vaccine equal to the state's percentage entitlement.
3. Vaccine manufacturers would limit their sale of vaccine in each state to the quota established for that state.
4. Manufacturers would report weekly to the Public Health Service the net amount of vaccine released for sale that week and, on a state-by-state basis, the amount shipped into each state in terms of amounts shipped to public agencies and to other purchasers.
5. The Public Health Service would maintain data from the states regarding the adequacy of available vaccine supplies under this system and would recommend modifications in the quotas if it appeared that supplies were exceeding demand in some states.

Dr. Burney reported that under this system the Public Health Service would not contemplate any allocation between public agency purchasers and commercial sales.

Whenever a vaccine is in short supply and the demand is great, it automatically creates problems of allocation and priority. How each state's share of its vaccine will be distributed is another aspect of the problem. The State and Territorial Health Officers, in a meeting on Aug. 28, recommended that priority be given to:

1. Those individuals whose services are necessary to maintain the health of the community.
2. Those individuals necessary to maintain other basic community services.
3. Persons with tuberculosis and others who in the opinion of the physician constitute a special medical risk.

In endorsing this priority recommendation, the A.M.A. Special Committee on Influenza suggests that state and local medical societies should consider the application of these recommendations on the basis of local conditions and situations. Local county medical societies should take the initiative in the organization of local advisory committees, composed of physicians, health officials, and representatives of other health groups, voluntary agencies, and civic organizations. Such local advisory committees would depend upon the local organizational plan adopted for their membership. They should be established to determine and recommend how the distribution should be made and in what order groups should receive it. Additional groups and categories should be added to the priority listing as the quantity of the vaccine is increased. It is highly desirable for individual physicians to adhere to locally established priorities under free and voluntary cooperative arrangements. Local advisory committees should publicize among the medical profession the priority system adopted and the basis for such determination. Industrial concerns, schools, and other special groups will also be guided by the recommendations established by local priorities. At the same time, an intensive public educational program should be instituted concerning the state vaccine allocation and priority program. This alone should relieve some of the pressure and clamor from individuals to their physicians for the vaccine.

In suggesting factors for consideration in the formulation of operational plans in the event an epidemic occurs, the Committee realizes that each state and each community will have to develop its own program within the framework of local practices, conditions, and resources and the particular difficulties confronting the community. The Committee visualizes the problem as basically a local one which can be met only by a carefully designed program tailored to local requirements with local health and medical groups working together in a team approach.

COUNCIL ON MEDICAL SERVICE

THE SENIOR CITIZEN AND HIS COMMUNITY

Frederick C. Swartz, M.D., Lansing, Mich.

This is the eighth of a series of papers on various aspects of aging. Each paper has been prepared for the Committee on Aging by an authority in the field. When completed, the series will be published in booklet form.

In every community, whether large or small, there is an increasing number of people being looked upon as senior citizens. A generation or two ago this group was not so large. The small community odd jobs and farming activities took care of many of those who could work. The family philosophy of being responsible for their own took care of a large part of the remainder.

As a "problem" the oldster did not present the urgency that is thought to be there today. In a community which throbs along at the relentless rate set by an atomic age, there is little sympathy or feeling for one who allegedly cannot keep the pace. We who have conquered the atom have not solved the challenge of being able to live one with the other. We are adept at recognizing differences that permit us to set groups apart and at discussing their special needs as problems; but what about those similarities which make us all brothers under the skin whether we are young or old, white or colored, religious or nonreligious.

The very title of the paper implies an ideal that the Committee on Aging might well strive to solve. The term "senior," besides indicating advanced age, carries with it the connotation of being advanced in accomplishments, dignity, rank, and office as well. It will be the responsibility of the aged of the future to possess these attributes. A citizen is a member of a free community and, in return for his loyalty and allegiance, is accorded protection of life, liberty, and property as well as the right to vote and speak regarding the affairs of government. The comunity then, for our purpose, is a number of citizens with a common organization and/or interest who live adjacently.

The real content of this paper, however, has to do with the people who are over 65 years of age and their relationship to the community in which they live. It does not take too much of a study to bring out the fact that far too many of the senior citizens have but one characteristic in common, and that is their age. The advanced accomplishments, dignity, rank, and office seem to have been lost somewhere. The interest in environment, motive for living, and the sense of belonging seem to be hardly worth the effort. Neglect of personal appearance, chronic complaining, and failure to keep mentally alert limit the horizons of personal association. Any exaggeration of these defects changes sympathy and understanding to neglect and disgust and provides motives for the segregation of aged in homes and institutions.

Allegiance and loyalty are still expected of the senior citizen by the community. The protection of life, liberty, and property become a mockery to many in the face of enforced compulsory retirement which denies the oldster that right which gave his whole life meaning prior to the age of 65—and that is the right to work.

In any labor market there is a sizable number of workers who have, for various reasons, never stayed long enough in one place to take root. These constitute the bulk of those who find it more and more difficult to get jobs as they approach 65 years of age. If the truth were known, they are largely the ones who would have difficulty getting employment on a tight labor market irrespective of their age. These should not constitute a part of the so-called problems of the senior citizens.

In this latter area, we have a totally different challenge. The rising cost of supporting the aged in retirement; the recognized value of the older worker from the standpoint of efficiency, spoilage, absenteeism, and loyalty; and the recognized wastefulness occurring when human resources are squandered at the age of 65 make us view with grave doubts the present concept of compulsory retirement. It is the responsibility of the community and of industry to provide work for those who are willing and able. This concept is so very ably expressed by President John Erik Jonsson of Texas Instruments Incorporated when he says, "Never hire anybody you don't expect to keep the rest of his working life." It is the responsibility of the aging worker to realize that he has been and will continue to be a member of a society that wants and needs what he has learned through his years of effort. An adequate earned income is certainly the right of every member of a community. Even in the aged group this should be commensurate with his contribution and certainly should be larger than that provided by the usual retirement allowances plus social security.

Member of the Committee on Aging of the American Medical Association and Chief of the Section of Medicine, E. W. Sparrow Hospital.

Much is made of the concept of there being no place for the oldster because of his failure to keep pace in the production line. But what good is a production line without the consumer! Henry Ford must have realized this a number of years ago when the automotive industry was in its infancy. He envisioned the great productive lines of the future as the inevitable result of progress. His contribution to the industrial problems of the day was not to find more leisure for the individual who is not trained to use it in the first place but to provide more units of his product at a cost within the reach of all. When this did not quite occur, he raised the daily wage of every member of his factory to $5 a day, an unheard of figure in those days. Instead of causing an economic collapse, it provided improvement in living standards of his employees as well as a greatly increased market for his automobiles. The great army of the retired which will grow larger with each advancing year is lost to the market because of inadequate income at the present time. Continued employment permits incomes above the usual retirement level and provides consumers with adequate funds to stimulate production.

Community planning and growth should take into consideration the needs of its older citizens. Some groups cling to the idea that these should take the form of a community for the aged within a community. Large multiple dwellings make it possible for similar needs to be met in group fashion. This is largely the approach observed in the so-called welfare state. There are several establishments of this variety being tried in the United States but with a somewhat different atmosphere. Fraternal, labor, or religious ties form the basis for this type of housing care. As nonsegregation becomes more prevalent, it is hoped that discrimination against the aged will become less articulate and the oldster will be able to take his place as a senior citizen and live and work in any part of the community he wishes. This privilege should continue until, because of either health or will, retirement becomes the course of choice. The future may still prove that a closer association of youth and age can be extremely beneficial to both.

Because of the decrease in infant mortality, and because many epidemic and endemic infections have practically disappeared from the scene, an increasing number of people are living to advanced years, and the profile of medicine has accordingly changed greatly. More opportunity exists for the application of theories of preventive medicine in an effort to further eliminate man's illnesses. More long-term illnesses also exist, especially among the aged, which make us review all our present methods of caring for the sick. Adequate medical care must be provided to keep the well oldster well; to keep the marginal oldster from becoming sick; and, when the oldster gets sick, to provide for his acute illnesses. The facilities of hospitals should be available as long as necessary in cases of acute illness, but then hospitals for chronic cases, rehabilitation centers, and convalescent nursing or old age homes are needed to complete the total care of the patient.

In summary, it seems that we are merely asking that the citizen who is entitled to vote and speak in his community be more advanced in dignity and standing and attainments and that his community recognize anew that the rights of citizenship be not abridged because of age.

BUREAU OF INVESTIGATION

BIMINI FUÉ DESCUBIERTO!!

IS "PEGA PALO" THE ANSWER?

According to the natives (and Webster, incidentally), Bimini was a fabulous island said to belong to the Bahama group, on which was located the Fountain of Youth.

When "el conquistador" Juan Ponce de Leon heard this, being a man of action, he took his company of Spanish adventurers and started out in earnest to claim it for the glory of Spain, and possibly to take a drink or two himself. Instead, the poor man discovered Florida. But there he found such an inhospitable group of natives that neither did he locate the Fountain nor did he get to build any fabulous hotels. Instead, he withdrew, mortally wounded, to Cuba.

This, of course, happened quite a few years ago. But legends such as this are extremely difficult to suppress, particularly when they have such an appeal, especially to the male of the species. This phenomenon was noted in The Journal in a report wherein Hess and his associates[1] observed, "The middle-aged man deplores his waning manhood and wants something done about it. He accepts the fact that he can no longer play a set of tennis or stay up all night at a party, but he will not gracefully accept his diminishing sexual vigor."

The verity of this observation is widely known, apparently. A lay publication which frequently devotes its columns to things sexual, and occasionally to things medical, published an article in a recent issue on the subject of "Pega Palo," a "vine that makes you virile." It was stated therein that the vine is native to the Dominican Republic and found only there, that the natives had used it for centuries, and that men of 80 acted like men of 30.

Although the island of Hispaniola (containing Haiti and the Dominican Republic) is not one of the Bahamas, it is near enough to provide a worthy locale for the discovery of such an important commodity. It goes without saying that the magazine enjoys wide circulation. A good many readers started casting about for a means to acquire the answer to their individual problem. A number of these persons, and perhaps others, wrote to this Bureau for information.

Pega Palo has been described to this Bureau variously, from a botanical standpoint. The Chicago distributors furnished the name Rhynchosia serpentine and later Paullinia sorbilis or cupana. Another source furnished indication that the vine is Rhynchosia pyramidalis. So far as is known, no active plant principle under any of these designations has been isolated or identified or been demonstrated to have any effect whatever as a drug.

It has been reported in the daily press that visitors to the Dominican Republic could obtain the material in hotels and gift shops and that Pega Palo had been processed into a concentrated liquid form, obtainable in very small bottles, for $3.50 to $5.00. Enterprising Americans, however, obtained quantities of the vine itself, and these were soon on the market, sold by mail for $15 for a cut of the vine approximately 8 in. long. In lots of eight, the bargain rate was $75. Purchasers of the vine were instructed to immerse it in a bottle of liquor—rum, bourbon, or whatever the purchaser had handy. After allowing the vine to "steep" for approximately eight days, the user should start with a 2-oz. "shot," and then continue according to his needs.

For obvious reasons, both the Federal Food and Drug Administration and the Post Office Department fraud division took umbrage, and each proceeded according to the laws it is obliged to enforce. The FDA has caused federal seizures of no less than nine lots of Pega Palo vines, charging misbranding by claims that the product is an aphrodisiac and that the labeling failed to bear adequate directions for use, and, further, that the sellers had failed to file a New Drug application. Such actions took place in federal court in Albuquerque, N. Mex.; Brooklyn, N. Y.; Chamberlain, S. D.; Chicago; Elyria, Ohio; Salt Lake City; and Yakima, Wash. Five of these cases have been closed on default decrees of condemnation and destruction. The four other cases are still pending.

The Post Office Department has announced the issuance of fraud orders against the Pega Palo Importers, Inc., the Roberts Company, the Lavergne Sales Company and Lavergne Sales, the Herbert Sales and the Herbert Sales Company, and the David Sales Company, all at Chicago. These fraud orders were dated June 19, 1957. Another, dated July 1, 1957, was issued against the B & E Distributing Company, at (of all places!) Bountiful, Utah. There is indication in the trade press that other fraud orders are in process.

Not so, however, with "Tintura de Pega Palo Fortidom," apparently now available on prescription as an experimental drug! The Bureau recently had occasion to confess its lack of knowledge on the subject of the Tintura (which appears to be a liquid extract), particularly as to the manner in which it is offered to physicians under an experimental program.

Recently, however, one physician quoted from a letter that he had received from a firm in Texas, in part as follows:

> . . . Tintura de Pega Palo Fortidom will not be available for personal use except through physicians until we have completed the investigational stages which we anticipate will be from eight to twelve months.
>
> It is preferred that the Tintura be mixed with a beverage of low alcoholic content such as wine. However, it may be mixed with soft drinks, milk, fruit juices, etc. It is intended that six tablespoons of the one to five mixture be taken three times daily for the first two days, resulting in the patient absorbing one and one-half tablespoons of Pega Palo the first day and one-half tablespoon the second day. Thereafter he should take a total of six teaspoons three times daily of the one to five mixture, resulting in his absorbing a total of three teaspoons of Pega Palo daily.
>
> We sincerely appreciate your interest and hope that you will decide to assist us in this project, as we have had a number of inquiries in G - - - - - -.
>
> Tintura de Pega Palo Fortidom can be furnished to you at $192.00 per gallon, which is $1.50 per ounce, or $50.00 a quart. It has been suggested that the patient be charged $3.00 per ounce, plus the regular charge for an office call, and that the patient be furnished from six to eight ounces at a time. However, this is entirely between the doctor and his patient.

From the above, it would not appear that the chief concern of the distributor is the obtaining of persuasive data to establish safety for use, the sole reason why new drugs are subject to testing under the federal act. This looks more like a sure-fire business proposition! A doctor who would participate in such a program would be obliged to tell his patients that their role as guinea pigs is in a rather nebulous field; they would be taking a product without identified drug properties!

Obviously, serious medical investigators would feel a lack of challenge in the premises, particularly when they are dealing with a preparation described by the "Tintura" promoters as "a product of Nature compounded with exacting care to enhance the natural zest for living." (It appears reasonable to assume that the Tintura de Pega Palo Fortidom is essentially the same as the Pega Palo vine now contraband in interstate commerce.)

But, assuming that there is reason to doubt the power of this alleged member of the Rhynchosia family to accomplish its Biminian purpose, there is, in a more recent issue of a magazine of similar character (identity unknown), an "exclusive" from Peru. This one is "Chuchiwasi," "the drink that can increase your virility." Again the reliance is on an alcoholic vehicle—which may account for the whole promotion.

MEDICINE AND THE LAW

AUTOPSY

This is the last in a series of six articles dealing with the necessity for and proper format of certain medicolegal forms. The subjects to be covered are (1) consent to operations and other medical procedures: (2) patient's right to privacy; (3) confidential communications and records; (4) artificial insemination; (5) the physician-patient relationship; and (6) autopsy.

This material has been prepared and will be published in book form by the Law Department of the American Medical Association under the title "Medicolegal Forms with Legal Analysis." The book will include extensive legal citations and a substantial number of additional forms which have not been included in this series of articles.—Ed.

After the death of a patient, his right to freedom from interference automatically passes in a modified form to his spouse or to his next of kin, and any unauthorized interference with his dead body exposes the offender to a suit for damages by the person entitled to its custody. One who participates in an autopsy to which the surviving spouse or next of kin has not consented and which is not authorized by law is also subject to criminal prosecution.

Generally, the person entitled to possession of a body for purposes of burial is entitled to authorize an autopsy upon it to determine the cause of death. The right to the body, and the attendant right to give or withhold consent to an autopsy, does not vest in the executor. The right vests in the surviving spouse, providing he or she was living with the deceased at the time of death in the normal relations of marriage. If the surviving spouse is not living with the deceased at the time of death in the normal relations of marriage, or if the surviving spouse waives the right, it will vest in the next of kin. So long as the surviving spouse asserts her rights to the body and does not abuse it, the next of kin have no rights with respect to the body and have no cause of action for the performance of an unauthorized autopsy on it. If there is no surviving spouse, the right vests in the next of kin, in order of kinship. Under such circumstances, a child of the deceased has rights superior to those of anyone else, unless it be the coroner or medical examiner. If the deceased is not survived by a child or children, authority over the dead body normally vests in the parents. It is not clear in those cases where the deceased child is a minor whether the consent of the father only is sufficient or whether the consent of the mother is also necessary. If the parents of the deceased minor child are divorced or separated, consent to the autopsy should be obtained from the parent who has custody of the child. In the absence of a child, children, or parents, authority over the dead body normally vests in brothers and sisters and so on through various degrees of consanguinity.

There are statutes in some states which provide for the order of the right to control of a dead body. The law has not undertaken to fix the relative rights of persons of equal degree of kinship, that is, the relative rights of several children, or of several brothers and sisters, and so on. Generally, it will be found that some one of a given group of children or brothers and sisters will be at the place of death and will assume charge of the body and it is to such a one that application should be made for permission to perform an autopsy.

In Wisconsin, there is a statute which provides that whoever of the near kin assumes custody of the body for burial purposes may give permission for autopsy. A Kentucky court has held that a physician is not liable where, without the consent of the relatives of the deceased, he performs an autopsy to determine the cause of death in order to comply with a statute which requires the physician's certification as to the cause of death. However, this does not appear to be the general rule.

The deceased may have left directions that an autopsy should be performed on his body. The trend of the American cases is to honor the deceased's directions as to the disposition of his body. There are statutes in a number of states providing that a person may, in his lifetime, direct what is to be done with his body after death. With the exception of the California statute, these provide that the authorization must be in writing; under the California statute, the direction must be in writing only if it directs that the remains are to be given to a teaching institution or hospital. In some states the workmen's compensation commission is permitted to order an autopsy when it is claimed that death resulted from an occupational cause. Sometimes an insurance policy will permit an autopsy and, in states recognizing such consents, the physician acting under such authority will be protected.

Authority of Coroner

In all jurisdictions, a public official, known either as the coroner or medical examiner, has legal authority to perform autopsies with respect to deaths due to other than natural causes. When death is due to violence or casualty or there is reasonable ground for believing that it has been caused in that way, the right to custody of a dead body vests immediately in the coroner or the medical examiner. When the coroner or medical examiner has legal control of a dead body his authority is supreme. He is entitled to the body in the condition in which it was at the moment of death. In general, he is authorized to perform or procure an autopsy on any body coming into his lawful custody.

It is, therefore, important that a physician should not undertake to perform an autopsy without the consent of the coroner or medical examiner in any case in which the body is properly within jurisdiction of such officer, even though the surviving spouse or next of kin may have consented. If the coroner or medical examiner authorizes the performance of an autopsy on a body which is not within his jurisdiction, he and those who perform the autopsy at his direction are liable to the surviving spouse or next of kin. Therefore, it is equally important for the physician that he undertake to perform no autopsy on the basis of authority from the coroner or medical examiner unless he is sure that the officer has jurisdiction over the body and power to authorize the autopsy. Where the jurisdiction of the coroner or medical examiner is doubtful, consent should also be obtained from the surviving spouse or next of kin.

Limitations on Autopsy

All autopsies must be performed in a manner which shows decent respect for the body. In the absence of a specific restriction, consent to an autopsy by implication authorizes the physician to conduct it in the usual and approved manner practiced by the profession and to remove for examination and study such parts as must be examined and studied in order to accomplish the purpose of the autopsy. However, authority to remove parts or organs for study and examination does not, in the absence of a specific agreement, include the authority to retain them permanently. If there is no specific authorization for retention of organs or parts of the body, those that have been removed must be replaced in the body cavity before interment. The person who has the right to authorize an autopsy has the right to state the limits within which it shall be performed, and the autopsy must be performed strictly within those limits.

Form of Consent

A number of states have statutes which provide that consent to an autopsy must be in writing. Although a nonwritten consent may be legally sufficient in some states, a physician should not perform an autopsy without having first obtained a specific written consent or authorization which he can produce as proof in the event of a subsequent challenge to his authority. As with consents to surgical operations, the consent to autopsy should be specific rather than general. If it is necessary or desirable to remove and retain parts of the body for further study and examination, even though they be but minute sections for microscopic study, specific consent should be obtained. Although it has been held that a physician may lawfully perform an autopsy under consent obtained in his behalf by some other person, the physician may best protect himself by personally obtaining the consent from those authorized to give it.

FORM 1.—*Authorization for Autopsy*

NAME OF DECEASED..AGE........SEX........

RACE............MARITAL STATUS............DATE OF DEATH............

1. I hereby authorize Dr.., and such persons as he may designate, to perform and attend a complete autopsy on the remains of.. for the purpose of determining the cause of death. Authority is also granted for the preservation and study of any and all tissues or parts which may be removed. This authority shall *be limited only by the following express conditions: (e. g.* "limited to abdomen," etc.)...

....

2. It is understood that due care will be taken to avoid mutilation or disfigurement of the body.

3. This authorization is given with the understanding that no charge will be made and that I will be informed of the results of this autopsy.

Signature of
next of kin..

Address..

City and
State...

Relationship to
the deceased...

Signature of
Witness...

Address...

City and
State... Date..................

Note. Next of Kin: For the purpose of this form the surviving spouse shall be considered the next of kin. In the absence of a surviving spouse, the next of kin shall be identified in accordance with the applicable State law.

FORM 2.—*Authorization for Tissue Donation*

To Dr...:

1. You are hereby authorized to remove the following tissues:..
(Insert: bone, artery, cartilage, skin, fascia, dura,
....from the remains of
nerve, tendon or eyes as desired.)
...., for donation of the aforementioned tissues to...
Authority is also granted to use the removed tissues in grafts upon living persons, or to otherwise dispose of these tissues in accordance with customary medical practice.

2. It is understood that due care will be taken to avoid unnecessary disfigurement of the body.

Signature of next of kin..

Address..

Relationship to the deceased..

Signature of witness.................................... Date....................

Address..

City and State..

Note. Next of Kin: For the purpose of this form the surviving spouse shall be considered the next of kin. In the absence of a surviving spouse, the next of kin shall be identified in accordance with the applicable State law.

FORM 3.—*Consent to Disposal of Dead Fetus*

Date....................

We hereby authorize and request.. to preserve for scientific purposes, or to dispose of, the dead fetus or the body of the baby born to.. on.., 19............, in accordance with customary medical practice. All claims to the body are hereby relinquished.

Signed..

Signed..

Witness..

Note. This consent should be executed by both parents, except that in the case of an unmarried mother her consent is sufficient.

MEDICAL-LEGAL PROBLEMS AND THEIR SOLUTIONS

In any discussion of medicolegal affairs it is advisable to reflect initially, if only briefly, on the fact that within the last 30 years the practice of medicine has become an increasingly complex undertaking, and during that period there has been a corresponding increase in related legal problems. The legal aspects of the patient-physician relationship have been complicated by many changes, including the practice of dividing the responsibility for the diagnosis, care, and treatment of patients with other physicians; the advent of group practice, of health insurance, and of contract practice; the growing number of circumstances in which the physician examines but does not treat, as in the examination of insured persons, of employees, of school children, of claimants of pensions, of claimants of damages for personal injury, and of persons accused of crimes; the increase in the number of physicians employed on a part-time or full-time basis; and the increase in the number of patients cared for through charity or by public funds.

Medical Professional Liability

Certainly one of the most important examples of legal complications in medical practice involves the subject of medical professional liability. Although not a new problem, it has, through a combination of recent circumstances, demanded an inordinate amount of attention from individual physicians and medical organizations. Some of the causes for this increased emphasis are the tendency of the public to seek financial remuneration for real or imaginary damage; the increasing tendency of juries to award more frequent and higher judgments; and inflation, necessitating higher payments for claims, judgments, and defense. The unfavorable articles in lay magazines dealing with the increased costs and medical care in general have created antagonism against the physician, while the favorable articles on new drugs, methods of treatment, and modern miracle surgery have in some instances been sufficiently exaggerated to lead the public to believe that a less than perfect result must be evidence of negligence.

What exactly then does the law require of a physician? It requires that when he undertakes to treat a patient he must possess and exercise the degree of knowledge, skill, and care commonly possessed and exercised by other reputable physicians in the locality. If he holds himself out as a specialist he must meet the standards of the specialist in his chosen field. He must keep abreast of progress in his profession and utilize standard and accepted methods and procedures in diagnosis and treatment. He must act with the utmost good faith toward his patient at all times. Of course he may not touch—certainly not operate upon—the patient without valid authorization. Further, his legal duty is not affected by the fact that his professional services are rendered gratuitously.

In a comprehensive report[1] prepared in 1941, Dr. Hubert W. Smith attempted to define the fundamental principles on which the legal status of the varied problems of medical professional liability must be determined. In his report he has outlined a rationale rather than a mere catalog of legal decisions.

In a more recent study[2] of the original sources of the law of professional liability, Dr. Andrew A. Sandor of California has analyzed all of the appellate court cases in the United States in the field from 1794 through 1955 with the exception of those resulting from counterclaims. His study shows not only the increased incidence of professional liability cases but also the areas of medical practice most vulnerable.

As impressive as Dr. Sandor's figures are with respect to reported cases, it must be remembered that they reflect only a small fraction of the claims and suits filed each year against physicians. In sional liability claims and suits and the availability and cost of liability insurance. Armed with these facts, we should be in a position to plan a long-range educational program for presentation to both the medical and legal professions.

The Law Department is continuing its study of this subject in other areas. An opinion survey among attorneys and members of the judiciary experienced in the handling of medical professional liability suits will be included. There will also be a study of insurance experience and rates and a survey of comparable fields of negligence actions.

The series of articles and reports that have appeared in The Journal between Feb. 2 and Oct. 5, 1957, will be published in booklet form and distributed by the American Medical Association.

Medical Expert Testimony

It is wrong in considering the availability of medical testimony to confine one's thinking to professional liability cases alone. This is so because it leaves the false impression that the medical profession has boycotted the courtroom in such actions. The actual facts are that the vast majority of doctors have an aversion to appearing in court and testifying in any kind of lawsuit. Although a few have had unpleasant experiences as witnesses, most have been frightened by the exaggerated reports of their colleagues of "murderous cross-examination" by opposing counsel.

In fairness to the physician, consideration must be given to the basic reasons behind this aversion. First, there is a fundamental difference in the method of approach of law and medicine so far as the discovery of truth is concerned. The lawyer attempts to maintain his position by argument and contention with opposing counsel. His life is one of advocacy of causes; his object is to magnify his own arguments and to belittle those of his opponent. The physician, on the other hand, does not live by contention. His training is in the free and open atmosphere of the laboratory, hospital, sickroom, or private office. He demands full and frank discussion and disclosure of all phases of a case. When all pertinent data are collected, he correlates them and forms a judgment. By training and practice, therefore, the whole tempo and attitude of the day-to-day experience of the physician and lawyer are totally different.

In addition to being unfamiliar with situations which to a lawyer are commonplace, physicians sometimes complain that they are made parties to the case in which they testify. This practice should, of course, be discontinued. Medical witnesses should testify concerning a certain set of facts and should never be made an advocate in the proceedings.

Another reason for the doctor's hesitancy to act as a witness is his failure to understand the concept of examination and cross-examination. It appears to the average medical witness that while one attorney is trying to establish the truth, opposing counsel is trying equally hard to keep the truth from being brought before the jury and court.

The physician also dislikes the time that court cases take from his daily activities—and it is not because he fears he might lose a fee. Physicians today are very busy people, with morning, afternoon, and sometimes all-night hours. The effect of stories about doctors cooling their heels in court for hours on end while lawyers argue seemingly obscure legal technicalities is difficult to overcome.

However, in the interest of the profession and particularly the public this hesitancy on the part of the physicians to testify must be overcome. The need for an all-out effort is obvious from the fact that from 65 to 80% of all cases tried today require medical testimony; that 7 out of 10 personal injury cases are decided on medical rather than legal considerations. During the past decade medicine has been making tremendous strides—amazing progress with surgery and with drugs. Doctors are now able to do new, unusual, and complicated procedures. Consequently when these procedures become germane to a litigated case, an ethical and qualified physician should be available and willing to testify. Juries cannot and should not evaluate these matters without expert medical advice.

Further, the role of the medical expert witness should not be played by a few. It is appalling to note the unprofessional and unethical actions of the few doctors who have become "professional witnesses" for plaintiffs and defense counsel. This new "medical specialty" is an injustice to the medical profession and to the public, and should be eliminated. In this endeavor the active assistance of the legal profession is imperative, for wherever a doctor testifies improperly there is at least one lawyer encouraging and misleading him.

Related Activities of Organized Medicine

The American Medical Association, with a membership of some 160,000 physicians, is concerned with many problems of medicolegal, social, economic, and political nature. Medical expert testimony is such a problem. It is one that has been of interest and concern to the medical profession for many years.

The proceedings of the House of Delegates of the American Medical Association, the policy-making body of the Association, contain many references to the subject. In 1914, a Committee on Expert Testimony reported after a three-year comprehensive survey of the entire field of medical expert testimony. The Committee's recommendations were to distinguish between matters of fact and matters of opinion, to place no restrictions on the testimony of fact, and to limit the testimony on opinion to those experts called by the court. The Committee recommended that the compensation of such experts should be fixed by the court and charged as a part of the cost of the case or against the party requesting the testimony. The Association accepted the report with the comment that "the solution to this vexing problem cannot be forced; it must come gradually and with the cooperation of the American Bar Association and the various state bar associations."

In 1929, the House of Delegates again adopted a resolution expressing its interest in the correction of the abuse of medical expert opinion evidence and offering cooperation to the American Bar Association and others in promoting the passage of legislation and in bringing about suitable changes in court procedure with reference to such evidence.

The American Medical Association has done more than just adopt resolutions on this matter. As an example, in October, 1955, the American Medical Association sponsored a series of three Regional Medicolegal Symposiums—in Chicago, Omaha, and New York City.

A part of the program at each meeting was designed to acquaint physicians with their essentiality in litigation and to dispel their fears of testifying in court.

To this end a demonstration of a mock trial was presented to show the wrong way and the right way for a physician to act in his role as a medical witness. The demonstration was repeated before medical and legal groups in 15 cities last year. In addition the members of the staff of the A. M. A. Law Department have presented talks on this subject at numerous medical or medicolegal meetings.

About two years ago, the Wm. S. Merrell Company, drug manufacturers in Cincinnati, and the Dynamic Film Corporation of New York saw the potential in the medical-legal field. They asked the A. M. A. to cooperate in the preparation of a series of six medicolegal films. After consultation with the American Bar Association, it was agreed to begin the project, and our demonstration of the physician as a medical witness was selected as the first topic. The second film, which was presented at the A. M. A. meeting in New York in June, deals with medical professional liability.

Again, in March of this year, the A. M. A. held another series of three regional medicolegal meetings—in Atlanta, Denver, and Philadelphia. Over 1,000 attorneys and physicians attended these meetings to hear and participate in a day-and-a-half discussion of three subjects: The Use of Chemical Tests for Intoxication in Court, Trauma and Cancer, and Medical Expert Testimony.

Committees for the Review of Medicolegal Testimony

Since its creation in August, 1954, the Law Department of the American Medical Association has received many inquiries from state and county medical societies desiring to initiate committees for the review of medicolegal testimony. Accordingly, each state society has recently been asked for information concerning the activity and experience that it or any of its county societies has had in organizing and maintaining such committees or in working on any other joint activities with the Bar Association.

The so-called Minnesota Plan was initiated in 1940 when a committee was appointed by the president of the Minnesota State Medical Association, with the approval of its council, to review those court cases in which medical testimony appeared to the court, to the attorneys, or to physicians to have been so contradictory as to indicate that one or more of the medical witnesses had consciously deviated from the truth.

Thereafter, the Illinois State Medical Society, the Kansas Medical Society, the Chicago Medical Society, and the Harris County Medical Society (Texas) established committees patterned after the Medical Testimony Committee in Minnesota. In addition to the above, the Louisiana, Indiana, and the Wisconsin Medical Societies have worked with their state bar associations in connection with the review of medicolegal testimony. The Medical Disciplinary Board Act of Washington provides for the review of medical testimony by the disciplinary board.

In some states and cities, committees or panels have been created for the purpose of providing the courts with impartial medical expert witnesses. About 15 years ago, the Los Angeles County Medical Association and the Los Angeles Bar Association jointly established a panel of physicians and surgeons to assist the courts in obtaining impartial medical testimony. Today, there are at least two physicians on the panel for selected specialties, or between 20 and 24 members. The panel physicians are selected by the joint committee of physicians and attorneys after each has indicated his willingness to examine the patient and testify. The court makes all the arrangements, including the establishment of time and place of examination and the compensation the physician is to receive. This cost is generally borne by the party who requests the appointment of the independent examiner. An impartial medical witness program is now in operation in New York County. A similar plan has been initiated by the Baltimore City Bar Association, the Maryland State Bar Association, and the Medical and Chirurgical Faculty of the State of Maryland.

In addition to the work of the medical societies, the American Bar Association, the state bar associations, the National Conference of Commissioners on Uniform State Laws, and many individuals within the legal profession have devoted their talents liberally in an effort to eliminate some of the problems associated with the use of expert witnesses. And, as I understand it, the consensus is that impartiality can best be achieved by somehow making the expert a neutral witness, not obligated in any way to either party. Two means for accomplishing this have been suggested: one by legislation, and the other by voluntary agreement.

The report and recommendations of the National Conference of Commissioners on Uniform State Laws, in 1936 and 1937, adequately describe both legislative and voluntary efforts to that date. The recent report[9] of the Special Committee of the Association of the Bar of the City of New York on its Medical Expert Testimony Project includes a review of voluntary programs and objectively and adequately describes the very excellent medical testimony project of the New York Bar.

Both reports bespeak the efforts of the bar to improve the quality of medical expert testimony. Yet, despite the continued and conscientious efforts of both professions it cannot be said that a solution has been discovered. None of the suggestions yet offered has had wholehearted acceptance by the judiciary, the bar, or the public.

Although the basic reluctance of physicians to testify in litigation generally is undoubtedly greater in medical professional liability cases, the reasons should not be hard to understand. Further, to assume that the medical profession is unique among professional groups in this regard is false. In a District of Columbia case, the judge stated: "Physicians, like lawyers, are loathe to testify that a fellow craftsman has been negligent, especially when he is highly reputable in professional character."[10]

The professions of law and medicine are both far from exact sciences. There is fortunately room for, and in practice there exist, in both professions, many different, equally valid opinions on a given set of facts. Both groups deal with complicated problems, the solutions to which can vary, in an individual case, on the basis of the most minute difference in circumstances.

In an address[11] presented in Dallas in August, 1956, Dr. Dwight H. Murray, who was then President of the American Medical Association, said in this regard:

> In medicine there has been, and I hope always will be, room for disagreement. Many procedures have their own adherents and when suggested therapy differs there will always be strong supporters for each approach. As an example, some doctors in setting a fracture prefer a slight offset of the bones on the theory that a stronger callus is formed. Others demand positive and complete alignment. Either can point out examples of his theory . . . walking, riding, swimming or golfing. Either honestly could express disagreement in private or on the witness stand, with the treatment given by the other.

These factors, when combined with the natural friendship and pride existing between members of the same profession, are bound to result in a reluctance on the part of a physician or an attorney to condemn publicly a fellow practitioner. If the opposite were true, the resulting professional climate would most certainly stifle legal and medical progress and establish a relationship between members of the professions and between the professional man and his patient or client which would seriously impede the administration of justice and impair the public health.

In areas where it is obvious that physicians or attorneys are neglectful of their obligations or are dishonest, then the two professions should work together to disfranchise those who make a mockery of justice. Licensure should be withdrawn by the state from the physician who sells his testimony to the highest bidder or shades it to the extent that he is paid. And by the same token, it follows that lawyers who engage in and encourage such physicians should likewise be denied the right to practice their profession.

Interprofessional Cooperation

Although members of both professions and medical and legal associations at the national, state, and local levels have had these matters of interprofessional concern under consideration for some time, it is only comparatively recently that concrete steps have been taken to solve them. Since 1954, the American Medical Association has greatly accelerated its efforts in the field of medicolegal relations to meet what it considers to be a growing desire on the part of the legal and medical professions to join in a sincere cooperative effort.

Medicolegal Conferences

As indicated earlier, the Association through its Committee on Medicolegal Problems and its Law Department has planned, encouraged, and participated in medicolegal conferences at the regional, state, and county levels. In developing the theme of these conferences, it was recognized that lawsuits are adversary proceedings and that conflict is a major element in the medicolegal field. Discussions and papers presented from the viewpoint of each profession proved that doctors and lawyers are both attempting to obtain the best results from individual and professional efforts. In presenting the view of medicine or law, every effort was made to clarify misunderstandings, not for the sake of understanding alone, but as a means to an end—the welfare of the individuals served, whether identified as patients, clients, or the public. At the regional meetings sponsored by the American Medical Association in 1955 and 1957, three broad areas of medicolegal relations were considered: medicine's contribution to the administration of justice; mutual medicolegal problems as viewed by each profession; and the role of a medical expert witness under proper and improper courtroom conditions.

In the area of the administration of justice there were provocative discussions on traumatic neurosis, trauma and disease, medical expert testimony, and medical science in the administration of criminal justice. In the area of medicolegal problems there were discussions of the several aspects of professional liability, a consideration of the professional man as a taxpayer, and an exploration of the best methods to insure unbiased medical expert testimony.

Medicolegal Liaison and Interprofessional Codes

The Cincinnati Bar Association and the Cincinnati Academy of Medicine were among the first groups to adopt formally an interprofessional code ("Standards of Practice Governing Lawyers and Doctors in Cincinnati"). This agreement, which contains a preamble and 12 brief paragraphs, covers with clarity and efficiency three of the most important problems affecting the two professions, namely, the obtaining of medical testimony, medical records, and provisions of adequate compensation to the physician for his services in connection with litigation.

Many other cities and states have followed their lead and have either adopted or are actively studying such a document. The codes, in general, contain provisions relating to written reports to be furnished by the doctor; conferences between physician and attorney prior to trial; arrangements made in advance for the physician to testify; the conduct of a physician while on the witness stand; and the compensation a physician should obtain for testifying. It is generally acknowledged that these codes will not, in and of themselves, eliminate interprofessional friction, but a continuing effort must be made if these problems are to be resolved.

In addition to such codes of understanding, the District of Columbia and 25 state medical societies have either established liaison with their bar associations or expect to do so in the near future.

Recently, the American Bar Association and the American Medical Association appointed a national medical-legal liaison committee. This is a step that is long overdue and should provide another effective link between two great professions.

Conclusions

It should be obvious to any conscientious and unbiased observer that an honest effort has been made during the past few years to improve the application of medical science in the administration of justice.

It is nevertheless still true that physicians in the practice of their profession have made and will continue to make their share of human errors, that physicians need to be educated to their responsibility to testify in court in various types of cases, that it is necessary to make a closer review of medical testimony of the type which is, unfortunately, solicited and presented, on occasion, for plaintiffs and defendants, and that a better rapport between the legal and medical professions is an absolute necessity. It is equally obvious that the mere existence of these facts and the need for improvement falls far short of the "medical conspiracy" which has been so glibly and irresponsibly alleged.

Persons who make charges of this type do not want ethical, objective, and impartial medical testimony available in all litigation—they prefer a further distortion of the theory of *res ipsa loquitur*, and an extension of the legally objectionable type of legislation that has been enacted in Massachusetts and Nevada. True, these mechanisms produce "second-rate" medical evidence, but that appears preferable, to some, to the presentation of proper medical facts.

The American Medical Association, the American Bar Association, and many of the state and local medical and legal societies are just now becoming sufficiently acquainted with the mutual problems of medicine and the law to initiate concrete efforts at better understanding. The success of these efforts requires the assistance of all ethical and honest physicians and attorneys in the best interests of the public as well as the professions.

MEDICAL NEWS

ARIZONA

Center for Heart Studies.—A center for special heart studies has been established at St. Luke's Hospital, Phoenix, through the cooperation of the hospital board of directors and the Greater Arizona Heart Association. The center will enlarge facilities that have been available at the hospital for two years. The facilities and service function around cardiac catheterization and angiocardiography. Because of limitations in personnel and funds, the center is not intended as a general consultation service in heart disease; however, funds have been used to establish an adequate armamentarium for cardiac surgery.

CALIFORNIA

Society News.—The Radiological Society of Southern California has elected the following officers for the coming year: chairman, Dr. Donald Laing, Pasadena; vice-chairman, Dr. George Jacobson, Los Angeles; secretary-treasurer, Dr. Harold P. Tompkins, 658 S. Westlake, Los Angeles 57.

Personal.—Dr. Francis R. Schwartz has been appointed regional medical director for United Air Lines at San Francisco, replacing Dr. Arthur C. Ladd, who has taken an extended leave of absence for postgraduate studies at Harvard University, Boston.

CONNECTICUT

University News.—The Yale University School of Medicine Arthritis Study Unit will present Dr. Alexander B. Gutman, speaking on "Pathogenesis and Management of Primary and Secondary Gout" at the Fitkin Amphitheater, New Haven, at 8:30 p.m. Oct. 17. All physicians are invited.

FLORIDA

University News.—The Miami Chapter of the Phi Delta Epsilon Fraternity will present a lecture at the University of Miami Medical School Oct. 17. Dr. William C. Stadie of Philadelphia will be the guest lecturer and will discuss "Metabolic Abnormalities in the Diabetic State."

ILLINOIS

General Practice Meeting in Springfield.—The 10th annual scientific assembly of the Illinois Academy of General Practice will be held Oct. 22-25 at the Illinois State Armory, Springfield. Dr. Orvan A. Phipps is president of the academy. The following panel discussions are scheduled: immunology, therapy in cardiovascular disease, and pediatrics—emergencies, accidents, and behavior. The program includes the following topics by out-of-state speakers:

Pain Patterns in the Diagnosis of Certain Upper Abdominal Diseases, Dr. Lucian A. Smith, Rochester, Minn.
Management of Cardiac Decompensation, Dr. Milton W. Anderson, Rochester, Minn.
The Allergic Patient—His Problems, Office Diagnosis and Treatment (Emphasis on Bronchial Asthma), Dr. Nathan Silbert, Lynn, Mass.
The All American Killer or National Hazard, Sgt. E. C. Paul, Indianapolis, Ind.
Cervical Biopsies in Office Practice, Drs. George S. Allen and Malcolm L. Barnes, Louisville, Ky.
Minor and Major Vascular Accidents, Dr. C. R. Hanlon, St. Louis.
Current Concepts in the Control of Urinary Tract Infections, Dr. Ian M. Thompson, Ann Arbor, Mich.

Scientific and technical exhibits are planned. Ten hours of category I credit will be given academy members for attendance. Entertainment includes the annual banquet Oct. 24 at the Hotel Leland. For information write the Illinois Academy of General Practice, 14 E. Jackson Blvd., Chicago 4.

Chicago

Society News.—The Chicago Neurological Society has elected the following officers for 1957-1958: president, Dr. Oscar Sugar; vice-president, Dr. John J. Madden; councilor, Dr. Irving C. Sherman; and secretary, Dr. Meyer Brown.——The Chicago Orthopaedic Society has elected the following officers: president, Dr. Earl S. Leimbacher; vice-president, Dr. Fred L. Stuttle; president-elect, Dr. Carlo S. Scuderi; secretary, Dr. William A. Larmon, 700 N. Michigan Ave., Chicago 11; and treasurer, Dr. Charles V. Heck.

IOWA

Iowa Journal Honors Dr. Bierring.—The August issue of the *Journal of the Iowa State Medical Society* was dedicated to the life and achievements of Dr. Walter L. Bierring, who served as president of the American Medical Association in 1934. Dr. Bierring, who also received the A. M. A. distinguished service award in 1956, has had a career which Dr. Joseph B. Priestley, of Des Moines, said parallels in many ways the life of Sir William Osler, whom Dr. Bierring knew well. Besides Dr. Priestley, authors of articles about Dr. Bierring were Drs. Daniel J. Glomset, now of Santa Barbara, Calif.;

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Fred Sternagel, West Des Moines; and Lieut. Col. Philip G. Keil, now of San Antonio, Texas. Dr. Priestley said, "A great teacher and scientist, Dr. Bierring [who is 89 years of age] has a never-aging mind and an alert vision for everything that is best in medicine. His name is a symbol of medical progress not only for us but for medical men throughout the United States and even in foreign countries."

KENTUCKY

College of Physicians Meeting in Lexington.—The Kentucky regional meeting of the American College of Physicians will be held at the Central Baptist Hospital, Lexington, Dec. 7. Dr. Dwight L. Wilbur, president-elect of the college, will present "The Third Person in Medicine" at the dinner meeting. Insurance will be discussed by Mr. Ralph O. Claypoole Sr., Philadelphia. The program includes the following papers:

Pulmonary Abscess—A Review of 70 Cases, Drs. Daniel N. Picker and William Ruoff, Louisville.
Migration of Potassium in Periodic Paralysis, Dr. Matthew C. Darnell, Lexington.
Multiple Myeloma in Siblings, Drs. Wallace E. Harrell and J. Douglas Ruff, Lexington.
Disability Evaluation in Chronic Pulmonary Disease, Drs. William H. Anderson, Harlan, and William F. Schmidt, Norton, Va.
Oral Hypoglycemic Agents: Current Status, Dr. Franklin B. Moosnick, Lexington.

For information write the American College of Physicians, 4200 Pine St., Philadelphia 4.

MASSACHUSETTS

Research Grants.—Boston University School of Medicine has recently received a total of $275,045 in grants for specialized research projects. Of this total, $150,099 represents a series of renewal grants from the National Institutes of Health for projects currently being carried on in the school's departments of dermatology, surgery, physiology, anatomy, biochemistry, and medicine. In addition, the school has received seven new awards totaling $124,946 from the National Institutes of Health and the United Cerebral Palsy Association for special studies in pediatrics, pharmacology, and physiology. Largest of the new research grants was an award of $38,880 by the National Institutes of Health for a study of potential cancer chemotherapeutic agents. Another new award will be used to carry on a study of the development of cerebral paralysis in infants and children under the direction of the department of pediatrics.

MINNESOTA

Society News.—At a recent meeting of the Minnesota Radiological Society, the following officers were elected for the coming year: Dr. David G. Pugh, president; Dr. Leo A. Nash, vice-president; Dr. Osmond J. Baggenstoss, 1953 Medical Arts Building, Minneapolis 2, secretary-treasurer.

Dr. Slater Honored.—Dr. Sidney A. Slater, a member of the board of the National Tuberculosis Association and superintendent of the Southwestern Tuberculosis Sanatorium in Minnesota, recently received two honors. The University of Richmond awarded him a Golden Legion Certificate of Merit "in recognition of 50 years of service to the university since his graduation in 1907," and the Minnesota Medical Association presented him with a citation of appreciation for "pioneer service in tuberculosis control."

MISSOURI

Personal.—Dr. John Earl Smith, commissioner, Division of Health, St. Louis Department, has received the 1957 W. Scott Johnson Award of the Missouri Public Health Association for "distinguished service in public health" in the state.——The following are members of the new State Mental Health Commission: Dr. Edmond F. Sassin, St. Louis; and Dr. Emerson D. Chaisson, Columbia.——Dr. Armand E. Brodeur has been named assistant dean of the St. Louis University School of Medicine. His duties will be in the area of student admissions and curriculum scheduling. Dr. Brodeur received a master's degree in radiology from the university in 1952.

General Practice Meeting.—The ninth annual scientific assembly of the Missouri Academy of General Practice will be held Oct. 30-31 at the Governor Hotel, Jefferson City. Symposiums on endocrinology, gastroenterology, and chest diseases are planned. Topics by out-of-state speakers include the following:

Newer Concepts of Achalasia (Cardiospasm) of the Esophagus, Dr. Nicholas Hightower, Temple, Texas.
Diagnosis and Treatment Relative to Carcinoma of the Esophagus, Dr. H. M. Pollard, Ann Arbor, Mich.
Hemoptysis in Older Men, Dr. Katharine Boucot, Philadelphia.
Bronchoscopy in Diagnosis of Diseases of the Chest, Dr. Herman J. Moersch, Rochester, Minn.
Present Place of Surgery in Heart Disease, Dr. Charles P. Bailey, Philadelphia.
Treatment of the Arrythmias, Dr. William A. Sodeman, Philadelphia.

Panel discussions will follow the formal presentations. Ten hours of category I postgraduate credit will be given academy members for attendance.

NEW YORK

Society News.—Officers of the Northeastern New York Radiological Society for the 1957-1958 year are as follows: president, Dr. Richard Batt, Glens Falls; vice-president, Dr. Kencil Mitton, Schenectady; secretary-treasurer, Dr. Irving Van Woert Jr., Albany.

Personal.—Dr. Sarah H. Hardwicke, former assistant director of Strong Memorial Hospital, Rochester, has been appointed by the United Mine Workers of

America to be associate clinical director for 10 memorial hospitals in Kentucky, West Virginia, and Virginia. She will take office Nov. 1 in Washington. Dr. Hardwicke also has been an instructor and assistant attending pediatrician at the University of Rochester, Strong Memorial Hospital, Cornell University, and New York Hospital.

Name President of Medical Center.—Appointment of Dr. Carlyle Jacobsen as president of the State University of New York Upstate Medical Center, Syracuse, has been announced. The title of president at the center is a new one, and both medical centers of the state university will have presidents whose duties will be commensurate with the established titles. Since 1950 Dr. Jacobsen has been executive dean for medical education at the university offices in Albany. Formerly he was on the faculty of the Washington University School of Medicine, St. Louis, and later was appointed dean of the Graduate College at the State University of Iowa. He is chairman of the Committee on Disaster Studies of the National Research Council, and also serves on the Committee on Educational Research and Services of the Association of American Medical Colleges.

Appoint Preventive Medicine Department Chairman.—The appointment of Dr. Harry A. Feldman as chairman, department of preventive medicine of New York State University College of Medicine, Syracuse, has been announced. A member of the College of Medicine faculty since 1949, Dr. Feldman has been professor of preventive medicine since 1956. Under his direction, the department has undertaken studies on the control of streptococcal infections in persons who have had rheumatic fever. Dr. Feldman also initiated a research program on the epidemiology of toxoplasmosis. He is a member of the board of directors of the Syracuse Rheumatic Fever Foundation, and Onondaga Health Association, a diplomate of the American Board of Internal Medicine and an associate member of the Commission on Respiratory Diseases of the Armed Forces Epidemiological Board.

New York City

University News.—The Gamma Chapter of the Phi Delta Epsilon Fraternity at The Columbia University College of Physicians and Surgeons will present the annual Clay Rae Murray Memorial Lecture Oct. 14, 8 p. m., at Bard Hall. Dr. George Crile Jr., of Cleveland, Ohio will discuss "Some Problems in the Treatment of Cancer."

PENNSYLVANIA

Personal.—Dr. Leo H. Criep, conducted a course on clinical allergy at the Hospital dos Servidores do Estado in Rio de Janeiro Aug. 19-23 as the invited guest of the Brazilian Government. This was in celebration of the 10th anniversary of the opening of this federally controlled hospital. He addressed the Brazilian Allergy Society and the Argentinian Allergy Society.

Philadelphia

Discussion of Asian Influenza.—A panel discussion, "The Asian Influenza of 1957," the first of a series on "Current Problems in Preventive Medicine," will be held at the Hall of the College of Physicians of Philadelphia at 4:30 p.m. Oct. 15. Participants include Dr. John J. Hanlon, chairman, department of preventive medicine and public health, Temple University School of Medicine, and Dr. Tom F. Whayne, professor of preventive medicine and public health, University of Pennsylvania School of Medicine.

Cancer Research at Woman's College.—Cancer of the cervix will be the subject of a new $300,000 research study at The Woman's Medical College of Pennsylvania. The study, conducted by the college in cooperation with the National Cancer Institute of the U. S. Public Health Service, will involve the examinations of some 50,000 women employed in industry each year over a three-year period. A modification of the Papanicolaou technique will be used. Approved by the Philadelphia County Medical Society, the Uterine Cancer Cytology Research project, as it is officially titled, will serve for case identification and research study only. A report on each examination will be forwarded to the woman's private physician, and any further diagnosis or treatment will be carried out by him.

WISCONSIN

Grant for Leukemia Research.—An initial $32,987 grant from the National Institutes of Health to support the first year of a five-year research program on leukemia by Prof. Harry A. Waisman of the University of Wisconsin Medical School, Madison, has been anounced. The grant is the first of five totaling $165,000 to be expended in the program. Dr. Waisman will study the changes in body chemistry which occur in human beings and animals when they develop leukemia, and will conduct research on the use of existing anti-leukemic drugs and new drugs as they become available.

GENERAL

Rhinologic Society Meeting.—The third annual meeting of the American Rhinologic Society will be held Oct. 18-19 at the Palmer House, Chicago, to be followed by a three-day clinical session in the Illinois Masonic Hospital, Chicago. A total of 14 papers are scheduled and will be followed by panel and open discussions. Papers will be presented by two guests of honor: Dr. Francis L. Lederer, head, department of otolaryngology, University of Illinois College of Medicine, who will speak on "Otolaryngological Heritage," and Dr. John E. Bordley, head, department of otolaryngology, Johns Hopkins Medical School, Baltimore, who will speak on "Respiratory Mucous Membrane." The annual dinner will be held Oct. 19 at which Dr. Walter E. Loch, president of the society, will be toastmaster. There is no registration fee. Members of the profession are welcome. For information write Mrs. Mabel Campbell, 830 Wellington Ave., Chicago 14.

Gastroenterology Meeting in Boston.—The 22d annual convention of the American College of Gastroenterology will be held Oct. 21-23 at The Somerset. Boston. Drs. Carlos J. Sanz and Lino Boudet, Havana, Cuba, will present "Incidence of Esophageal Varices in Cirrhosis" the evening of Oct. 23. The program includes the following panel discussions and moderators:

Ulcerative Colitis, Dr. Everett D. Kiefer, Boston.
Diseases of the Esophagus, Dr. Franz J. Ingelfinger, Boston.
Peptic Ulcer, Dr. Seymour J. Gray, Boston.
Management of Massive Gastrointestinal Hemorrhage in Patients with Liver Disease, Dr. Norman Zamcheck, Boston.

A motion picture program and scientific and technical exhibits are planned. Entertainment includes the 25th annual banquet Oct. 22. A ladies' program has been arranged. For information write Mr. Daniel Weiss, executive director. American College of Gastroenterology, 33 W. 60th St., New York City.

Dietetic Association Meeting in Miami.—The American Dietetic Association will hold its 40th annual meeting in Miami. Fla., Oct. 22-25. Daytime sessions will take place at the Dinner Key Auditorium, where the exhibits of food and equipment companies will be on display. Speakers include Dr. Robert E. Shank, St. Louis; Dr. Rachmiel Levine, Chicago; Dr. Robert E. Olson, Pittsburgh; Dr. Walter M. Hamburger, New York City; Dr. Theodore B. Van Itallie, Boston; Miss Jane C. Ebbs,' Washington, D. C.; Mr. Keith A. Fitch, Atlanta, Ga.; Walter O. Walker, Ph.D., Coral Gables, Fla.; J. P. Lesperance, Ph.D., Coral Gables; Warren Guthrie, Ph.D., Cleveland; and James M. Godard, Ph.D., Miami. Major topics to be discussed include dietary allowances, treatment of diabetes, obesity, current research, food administration, refrigeration, communications and human relations, community nutrition, and education. For information write the American Dietetic Association, 620 N. Michigan Ave., Chicago 11.

Safety Congress in Chicago.—The 45th national safety congress, sponsored by the National Safety Council, will be held Oct. 21-25 at the Conrad Hilton, Sheraton-Blackstone, Congress, Hamilton, La Salle, and Morrison hotels, Chicago. Major General B. K. Young, director-general, of The Royal Society for the Prevention of Accidents, London, England, will present an address Oct. 21. A panel discussion to be held Oct. 23 will include the following subjects: engineering and statistical consultation, National Safety Council awards. supervisor development, programming of employee materials, and section activities. Safety films awards will be presented Oct. 22. The 12th annual federal safety conference. sponsored by the Federal Safety Council. will be held Oct. 21-22, as part of the national congress. Entertainment includes a banquet Oct. 23. Registration fee is $5. For information write the National Safety Council, 425 N. Michigan Ave., Chicago 11.

Angiology Meeting in Atlantic City.—The third international congress of the International Society of Angiology will be held at the Ambassador Hotel, Atlantic City, N. J., Oct. 18-21. Dr. Leroy Burney, surgeon general, U. S. Public Health Service, will present an address on Oct. 19. The presidential address will be Oct. 20 by Dr. A. Mario Dogliotti, Turin, Italy. The program includes the following symposiums: management of coronary artery disease, management of aneurysms of the aorta and major arteries of the extremities, management of arteriosclerotic occlusions of the aorta and major arteries of the extremities, and arterial replacements. Speakers from Belgium, France, Canada, Rumania, England, Germany, Brazil, Italy, Cuba, Uruguay, Poland, Sweden, Greece, and the U. S. are scheduled. Simultaneous translations in French, Spanish. and English will be available at all sessions. Motion pictures will be shown each morning and afternoon, running concurrently with the scientific sessions. Scientific and technical exhibits are planned. For information write Dr. Henry Haimovici, Secretary-General, International Society of Angiology, 105 E. 90th St., New York 28, N. Y.

Gulf Coast Clinical Meeting.—The 17th annual meeting of the Gulf Coast Clinical Society will be held Oct. 17-18 at the Buena Vista Hotel, Biloxi, Miss. The program includes the following topics and speakers:

Application of Radioactive Isotopes to Certain Problems of Interest to Practitioners of Medicine, Dr. Arthur L. Kretchmar, research clinician, Oak Ridge, Tenn.
Autonomic Nervous System and Symptomatology, Dr. Eugene Stead, professor of medicine, Duke University, Durham, N. C.
What's New in Obstetrics and Gynecology, Dr. J. P. Greenhill, senior attending obstretician, Cook County Hospital, Chicago.
Common Behavior Problems in Children and What to Do About Them, Dr. Richard E. Wolf, Children's Hospital, Cincinnati, Ohio.
Pathogenesis of the Postgastrectomy Syndrome, Dr. George H. Peddie, clinical instructor in surgery, Baylor University College of Medicine, Houston, Texas.
Early Management of Tendon Injuries of the Extremities, Dr. Robert A. Knight, assistant professor of orthopedic surgery, Campbell's Clinic, Memphis, Tenn.

A clinicopathological conference will be conducted Oct. 18, by Dr. Walter Sheldon. Emory

University, Atlanta, Ga. A banquet will be held Oct. 17. For information write the Gulf Coast Clinical Society, 200 West Jackson St., Biloxi, Miss.

Meeting of Life Insurance Medical Directors.—The 66th annual meeting of the Association of Life Insurance Medical Directors of America will be held Oct. 23-25 at the Hotel Statler, New York City. On Oct. 25 a discussion will be conducted on "Professional and Public Relations" by the following persons: Dr. Albert L. Larson, Travelers Insurance Company; Dr. Frank A. Warner, John Hancock Mutual Life Insurance Company; Dr. William O. Purdy, Equitable Life Insurance Company of Iowa; Dr. Frank J. McGurl, Prudential Insurance Company; and Dr. Charles D. Gossage, Confederation Life Association. The program includes the following topics and speakers:

Status of Radiation Safety in 1957, Dr. Reynold F. Brown, San Francisco.
Hematologic Disorders: Their Disabilities and Prognosis, Dr. Paul Reznikoff, New York City.
Diagnosis, Prognosis, and Treatment of Hypertensive Cardiovascular Disease, Dr. Robert W. Wilkins, Boston.
Hypertension in Substandard Insurance, Dr. Albert A. Pollack, New York City.
Mortality Study in Hypertension, Drs. William Bolt, Jack R. Barnes, and Murray F. Bell, New York City.
Effect of Myocardial Disease and Dysfunction on the Form of the Electrocardiogram, Dr. Charles E. Kossmann, New York City.
Recent Advances in Surgical Correction of Congenital Heart Lesions, Dr. Charles P. Bailey, Philadelphia.
Economics of Health Care, Dr. Howard L. Hauge, Mr. Albert V. Whitehall, and Dr. Percy E. Hopkins.

A reception will be held at 6 p. m., Oct. 23, to which ladies are invited. For information write Dr. Royal S. Schaaf, Secretary, the Association of Life Insurance Medical Directors, P. O. Box 594, Newark 1, N. J.

Fellowship in Dermal Pathology.—The Earl D. Osborne fellowship in dermal pathology, sponsored by the American Academy of Dermatology and Syphilology, provides annually the opportunity for study and training in dermal pathology to a postgraduate student who has completed satisfactorily at least one year or preferably two years of training in dermatology. The stipend is $4,000 a year, divided into four quarterly payments during the year's fellowship. The period of training will be spent at the Armed Forces Institute of Pathology, Washington, D. C., the appointment being subject to approval by the director of the institute. A student must complete one year of graduate training, either before or after completion of the Osborne fellowship, in an institution approved by the board for three years of training. Application blanks may be obtained from Dr. Hamilton Montgomery, Chairman, Committee on Pathology, American Academy of Dermatology and Syphilology, 200 First St. S. W., Rochester, Minn. The next available appointment begins July 1, 1958. Early application is urged and as a rule applications will not be considered after Sept. 1.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

CORRECTIONS

Dr. Rosenblum Goes to North Carolina.—Concerning the news item under this heading in The Journal Aug. 17, page 1827, Dr. Bernard F. Rosenblum has written that the following part of the item was erroneous: "He will also serve as associate professor of public health administration in the School of Hygiene and Public Health at the University of North Carolina, Chapel Hill, and as associate professor of medicine at Duke University, Durham."

Recurring Infectious Thrombophlebitis.—In the Query and Minor Note "Recurring Infectious Thrombophlebitis," The Journal, Aug. 17, 1957, page 1857, in the third paragraph, "either Parenzyme or Chymar, 5 Gm. daily for a series of 10 treatments" should have read, "either Parenzyme or Chymar, 5 mg. daily for a series of 10 treatments." This may be given as one dose daily or may be divided into two doses of 2.5 mg. each. In some extreme cases, it may be given in doses of 2.5 mg., four times a day, but, in the average case, 5 mg. daily should be effective.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 17-19. Sec., Dr. D. G. Gill, State Office Building, Montgomery 4.

Arizona:* *Examination and Reciprocity.* Phoenix, Oct. 16-18. Exec. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 7. Sec., Dr. Joe Verser, Harrisburg.

California: *Written Examination.* Sacramento, Oct. 21-24. *Oral Examination.* San Francisco, Nov. 16. *Oral and Clinical for Foreign Graduates.* San Francisco, Nov. 17. Sec., Dr. Louis E. Jones, 1020 N St., Sacramento 14.

Colorado:* *Examination.* Denver, Dec. 3-4. Exec. Sec., Mrs. Beulah H. Hudgens, 715 Republic Bldg., Denver 2.

Connecticut:* *Examination.* Hartford, Nov. 12-14. Sec., Dr. Creighton Barker, 160 St. Ronan St., New Haven.

Delaware: *Examination.* Dover, Jan. 14-16. *Reciprocity.* Dover, Jan. 23. Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:* *Examination.* Washington, Nov. 12-13. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington, D. C.

Florida:* *Examination.* Miami, Nov. 24-26. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Idaho: *Examination and Reciprocity.* Boise, Jan. 13-15. Ex. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Iowa:* *Examination.* Des Moines, Dec. 2-4. Exec. Sec., Mr. Donald V. Saf, State Office Building, Des Moines 19.

Kentucky: *Examination.* Louisville, Dec. 9-11. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Maine: *Examination.* Portland, Nov. 12-14. *Reciprocity.* Portland, Nov. 12. Sec., Dr. Adam P. Leighton, 142 High St., Room 514, Portland.

Maryland: *Reciprocity.* Baltimore, September. *Examination.* Baltimore, Dec. 10-13. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore.

Massachusetts: *Examination.* Boston, Jan. 14-17. Sec., Dr. Robert C. Cochrane, 37 State House, Boston.

Minnesota:* *Examination and Reciprocity.* Minneapolis, Oct. 15-17. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. *Examination.* Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Old Capitol, Jackson 113.

Nebraska:* *Examination.* Omaha, June. Sec., Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

New Jersey: *Examination.* Trenton, Oct. 15-18. Sec., Dr. Patrick H. Corrigan, 28 W. State St., Trenton.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

GOVERNMENT SERVICES

VETERANS ADMINISTRATION

Increased Compensation for Veterans.—Public Law 85-168 authorizes for more than 2 million disabled veterans higher compensation checks for service-connected disabilities, starting with checks mailed out at the end of October, 1957, the Veterans Administration said on Aug. 27.

Veterans already on the VA's compensation rolls need take no action to get the raise. It will be paid automatically. Also increased will be the special allowances for dependents of paid veterans whose service-connected disabilities are rated at 50% or more. With a few exceptions, the increase will be about 10% across the board, except for totally disabled veterans rated at 100%, whose boost from $181 to $225 per month amounts to 24.3%.

TABLE 1.—*Old and New Wartime Compensation Rates*

	Service-connected Disability, %	Wartime Rate*	
		Old, $	New, $
(a)	10	17	19
(b)	20	33	36
(c)	30	50	55
(d)	40	66	73
(e)	50	91	100
(f)	60	109	120
(g)	70	127	140
(h)	80	145	160
(i)	90	163	179
(j)	Total disability	181	225
(k)	Anatomic loss, or loss of use, of a creative organ, or 1 foot, or 1 hand, or both buttocks, or blindness of 1 eye, having only light perception, rates (a) to (j) increased monthly by	47	47
	Anatomic loss, or loss of use, of a creative organ, or 1 foot, or 1 hand, or both buttocks, or blindness of 1 eye, having only light perception, in addition to requirement for any rates in (l) to (n), rate increased monthly for each loss, or loss of use of, by	47†	47‡
(l)	Anatomic loss, or loss of use, of both hands, or both feet, or 1 hand and 1 foot, or blind both eyes with 5/200 visual acuity or less, or is permanently bedridden or so helpless as to be in need of regular aid and attendance, monthly compensation	279	309
(m)	Anatomic loss, or loss of use, of 2 extremities at a level, or with complications, preventing natural elbow or knee action with prosthesis in place, or suffered blindness in both eyes, rendering him so helpless as to be in need of regular aid and attendance, monthly compensation	329	359
(n)	Anatomic loss of 2 extremities so near shoulder or hip as to prevent use of prosthetic appliance, or suffered anatomic loss of both eyes, monthly compensation	371	401
(o)	Suffered disability under conditions which would entitle him to 2 or more rates in (l) to (n), no condition being considered twice, or suffered total deafness in combination with total blindness with 5/200 visual acuity or less, monthly compensation	420	450
(p)	In event disabled person's service-incurred disabilities exceed requirements for any of rates prescribed, Administrator, in his discretion, may allow next higher rate, or intermediate rate, but in no event in excess of	420	450
(q)	Minimum rate for arrested tuberculosis	67	67

* Compensation for disabilities incurred under non-extrahazardous conditions during peacetime are 80% of the wartime rate.

† But in no event to exceed $420 in combination with other applicable ratings.

‡ But in no event to exceed $450 in combination with other applicable ratings.

Unchanged are three statutory rates, two of them at $47 each, involving the anatomic loss, or loss of use, of one part of the body, and the third, at $67 as the minimum rate for arrested tuberculosis. These rates may be payable in addition to the percentage ratings for service-connected disabilities.

Compensation rates payable to veterans whose service-connected disabilities were suffered during peacetime service under non-extrahazardous conditions are 80% of the new wartime rate. Peacetime service disabilities suffered under extrahazardous conditions may be payable at the wartime rates.

Not affected by the increase are the compensation rates paid survivors of veterans whose deaths were service-connected, nor pensions paid wartime veterans or their widows or children for non-service-connected disability or death.

Both old and new wartime rates of compensation paid to veterans for service-connected disabilities are shown in table 1.

Allowances for Dependents.—Veterans whose service-connected disabilities are rated at 50% or more are entitled to additional compensation for dependents.

TABLE 2.—*Additional Disability Compensation for Dependents*

Dependency	Wartime Rate*	
	Old, $	New, $
Wife and		
No children	21	23
1 child	35	39
2 children	45.50	50
3 or more children	56	62
No wife and		
1 child	14	15
2 children	24.50	27
3 or more children	35	39
Dependent parents		
1	17.50	19
2	35	38

* If the disability was incurred under non-extrahazardous conditions during peacetime, additional compensation for dependents is 80% of the wartime rate.

Both the old and new wartime rates are listed in table 2; they are based on 100% disability. The rates for 50% or more are payable at the same ratio that the degree of disability bears to 100%.

Personal.—Dr. Frank J. Schaffer, chief, physical medicine and rehabilitation service, VA Medical Teaching Group Hospital, Memphis, Tenn., has been appointed chief of program development in the same service at Washington, D. C. Dr. Schaffer is certified by the American Board of Physical Medicine and Rehabilitation. He joined the VA in September, 1946, and has served at VA Hospitals in Fort Lyon, Colo., Fort Thomas, Ky., Columbia, S. C., and at the VA regional office in Albuquerque, N. Mex. Among his responsibilities in Washington will be the further development of the career residency program in physical medicine and rehabilitation, which is the second largest career residency program in the VA.

DEATHS

Hassett, Florence Sullivan ⊕ Elmira, N. Y.; born in Elmira, Sept. 28, 1903; University of Rochester School of Medicine and Dentistry, Rochester, N. Y., 1929; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past-president of the Chemung County Medical Society; past-president of the medical conference of Rochester Regional Hospitals Council; clinical instructor in medicine at his alma mater; attending physician and physician in charge of electrocardiographic laboratory. Arnot-Ogden Memorial Hospital; consulting physician, past-president of staff, and director of postgraduate education program, St. Joseph's Hospital; consulting physician and member of medical advisory board, Veterans Administration Hospital in Bath; past medical director and president of board of managers, Chemung County Sanatorium; died suddenly, July 6, aged 53, of dissecting aneurysm of the aorta.

Alter, Robert Leonhardt ⊕ Toledo, Ohio; born in Toledo March 8, 1913; Duke University School of Medicine, Durham, N. C., 1937; certified by the National Board of Medical Examiners; specialist certified by the American Board of Obstetrics and Gynecology; interned at the Johns Hopkins Hospital in Baltimore, where he served a residency at the Baltimore City Hospital; formerly a resident in obstetrics and gynecology at the Duke Hospital in Durham, N. C., and instructor in obstetrics and gynecology at his alma mater, where he was later assistant professor of obstetrics and gynecology; formerly professor and head of the department of obstetrics and gynecology at the American University of Beirut School of Medicine in Lebanon; fellow of the International College of Surgeons and the American College of Surgeons; died in Modesto, Calif., Aug. 7, aged 44.

Hawley, Sydney James ⊕ Seattle; born in Seattle Sept. 28, 1899; University of Pennsylvania School of Medicine, Philadelphia, 1924; formerly clinical assistant professor of Radiology, University of Washington School of Medicine; certified by the National Board of Medical Examiners; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America, of which he was president-elect and member of the board of chancellors of the American College of Radiology; past-president of the Pacific Northwest Radiological Society; formerly vice president of the American Registry of X-Ray Technicians; served on the staff of the Geisinger Memorial Hospital in Danville, Pa.; died in the Swedish Hospital July 29, aged 57, of coronary occlusion.

Breitstein, Moses Lewis, Baltimore; born in Richmond, Va., Nov. 18, 1894; Johns Hopkins University School of Medicine, Baltimore, 1919; specialist certified by the American Board of Otolaryngology; an associate member of the American Medical Association; fellow of the American College of Surgeons; an otologist for the city health department; consultant in otology for the Maryland State Department of Education; president of the Baltimore Hearing Society; associated with the Hospital for Women of Maryland, the Baltimore Eye, Ear and Throat Hospital, and the Union Memorial Hospital, where he died July 20, aged 62, of coronary heart disease.

Card, Daniel Parker, Colonel, U. S. Army, retired, Washington, D. C.; born in Smyrna, N. Y., July 29, 1878; University and Bellevue Hospital Medical College, New York City, 1904; fellow of the American College of Surgeons; service member of the American Medical Association; veteran of World War I; entered the medical corps of the U. S. Army in 1909 and retired July 1942; held the Legion of Merit; a Chevalier of the French Legion of Honor; decorated by Poland, Italy, and Serbia; for three years chief physician at Virginia Military Institute, Lexington, Va.; died in the Walter Reed Army Hospital July 24, aged 78, of cancer.

Ryan, Frank Kevan, Plattsburgh, N. Y.; born in Plattsburgh Dec. 12, 1890; George Washington University School of Medicine, Washington, D. C., 1916; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; past president of the Clinton County Medical Society; during World War I a surgeon with the British Expeditionary Forces and later served with the U. S. Army Medical Corps overseas for 16 months; a member of the staff of the Physicians Hospital; served on the staff of the Champlain Valley Hospital, where he died July 18, aged 66.

Garr, Charles Crain, Lexington, Ky.; Hospital College of Medicine, Louisville, 1907; specialist certified by the American Board of Orthopedic Surgery; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; an associate member of the American Medical Association; fellow of the American Col-

lege of Surgeons; veteran of World War I; formerly chief surgeon for the Chesapeake and Ohio Railway; on the staff of the Good Samaritan Hospital and St. Joseph Hospital, where he died July 28, aged 72, of acute gangrenous cholecystitis.

Burg, Fred Allan ⊛ Sanger, Calif.; University of Oklahoma School of Medicine, Oklahoma City, 1939; served an internship and residency at the General Hospital of Fresno County in Fresno; for three years on the board of governors of the Fresno County Medical Society; formerly member of the city council; served on the staffs of the Fresno Community and Valley Children's hospitals in Fresno and the Sanger Hospital; died Aug. 8, aged 41, of coronary occlusion.

Arndt, Oscar H., Detroit; Detroit College of Medicine, 1906; died July 11, aged 78, of coronary thrombosis and arteriosclerotic heart disease.

Bayliss, George William, Martinsburg, W. Va.; College of Physicians and Surgeons, Boston, 1906; died in the City Hospital May 28, aged 83, of acute coronary disease.

Bentz, George Henry, Saugerties, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1903; died May 6, aged 75, of carcinoma of the mouth with metastases.

Berg, Albert Page ⊛ Philadelphia; Medico-Chirurgical College of Philadelphia, 1901; served in France during World War I; died July 20, aged 78, of abdominal carcinomatosis.

Biggs, Ray Hoyt ⊛ Sanatorium, Miss.; Emory University School of Medicine, Atlanta, 1933; member of the American Trudeau Society; at one time health officer of Madison County; formerly assistant superintendent and medical director of the Mississippi State Tuberculosis Sanatorium; died July 12, aged 50, of emphysema and cor pulmonale.

Blackburn, Arthur Dale ⊛ Circleville, Ohio; Miami Medical College, Cincinnati, 1902; retired July 1, 1936 as Pickaway County health commissioner; died July 17, aged 77, of acute pulmonary edema.

Blumstein, David Barnett, Miami Beach, Fla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; formerly practiced in New York City; died in the Mount Sinai Hospital July 21, aged 74, of acute myocardial infarction.

Bresky, Hillard, Rego Park, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1924; member of the Medical Society of the State of New York; died Aug. 2, aged 58, of cancer.

Bussell, Benjamin Randolph ⊛ Waycross, Ga.; Atlanta College of Physicians and Surgeons, 1911; past president of the Ware County Medical Society; for many years chief anesthetist at Ware County Hospital; died in the Memorial Hospital July 14, aged 72, of cerebral thrombosis.

Carryer, Carl Haddon ⊛ Des Moines, Iowa; Barnes Medical College, St. Louis, 1902; chief of staff, Booth Memorial Hospital; on the staffs of the Iowa Lutheran and Mercy hospitals, and the Iowa Methodist Hospital, where he died July 20, aged 76.

Cohen, David, Louisville, Ky.; Kentucky University Medical Department, Louisville, 1903; an associate member of the American Medical Association, served in France during World War I; on the courtesy staffs of Kentucky Baptist Hospital, St. Joseph Infirmary, Jewish Hospital, and Norton Memorial Infirmary, where he died July 27, aged 74, of hypertensive cardiovascular disease.

Corrington, Dale Donatus, Tallassee, Ala.; Rush Medical College, Chicago, 1924; member of the Medical Association of Alabama; veteran of World War I; on the staff of the Community Hospital in East Tallassee, where he died July 21, aged 59, of chronic nephritis and uremia.

Crispo, Pierre Timothy ⊛ Fall River, Mass.; Laval University Faculty of Medicine, Quebec, Quebec, Canada, 1893; formerly school physician; for 12 years served on the board of health, the last six years as chairman; on the staff of St. Anne's Hospital; died in the Truesdale Hospital July 22, aged 85, of cerebral thrombosis.

Delagoa, Arthur Clark, San Antonio, Texas; University of Texas School of Medicine, Galveston, 1932; died July 21, aged 47, of peritonitis and enterocolitis.

Denham, Thomas William, Visalia, Calif.; Kentucky University Medical Department, Louisville, 1905; died in Tulare July 1, aged 74, of myocardial infarction.

Donker, Adrian Edward, Carrington, N. D.; Grand Rapids (Mich.) Medical College, 1907; died in the Carrington Hospital July 29, aged 75, of gastrointestinal hemorrhage.

Emerson, William Joseph ⊛ Laredo, Texas; George Washington University School of Medicine, Washington, D. C., 1944; certified by the National Board of Medical Examiners; chief of staff and director of pathology at Mercy Hospital; died July 5, aged 40.

English, Kinsey Ourant ⊛ Chicago; Rush Medical College, Chicago, 1930; member of the American Academy of General Practice; veteran of World War I; on the executive medical staff, West Surban Hospital, Oak Park, Ill., where he died Aug. 6, aged 62, of acute coronary disease.

Eveleth, George S., Newport, N. H.; Bellevue Hospital Medical College, New York City, 1888; member of the Medical Society of the State of New

York; an associate member of the American Medical Association; formerly practiced in Little Falls, N. Y., where he was on the staff of the Little Falls Hospital; died July 22, aged 92.

Fuller, Martin Luther, Abilene, Texas; Baylor University College of Medicine, Dallas, 1908; formerly director of the Laredo-Webb County Health Department; died July 19, aged 79, of cerebral hemorrhage.

Furby, Robert Ludwick, Vancouver, Wash.; University of Illinois College of Medicine, Chicago, 1913; died July 24, aged 72, of coronary occlusion and hypertensive cardiovascular disease.

Fuson, Carl Campbell ⊕ Milliken, Colo.; Denver and Gross College of Medicine, 1910; served in France during World War I; on the staff of the Weld County General Hospital, where he died July 16, aged 78.

Galloway, Fletcher Wilson ⊕ Florala, Ala.; Memphis (Tenn.) Hospital Medical College, 1903; died July 10, aged 84, of a heart attack.

Gilliland, Alvin Orrin, Cameron, Mo.; Kansas City (Mo.) Medical College, 1903; died July 17, aged 78, of coronary thrombosis.

Gottschalk, Clara Grace ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1915; died July 21, aged 74, of acute pulmonary edema and arteriosclerotic heart disease.

Grundset, Ole J. ⊕ Montrose, Minn.; College of Medical Evangelists, Loma Linda and Los Angeles, 1927; died June 30, aged 70.

Halbrook, John Franklin, Morrilton, Ark.; Memphis (Tenn.) Hospital Medical College, 1902; past-president of the Conway County Medical Society; veteran of World War I; died in Veterans Administration Hospital, North Little Rock, June 18, aged 83, of cerebral thrombosis and arteriosclerosis.

Hopkins, Richard Thomas ⊕ Orofino, Idaho; Cornell University Medical College, New York City, 1909; served on the staff of the Orofino Hospital; died in Portland, Ore., July 29, aged 74, of cancer.

Hopson, George ⊕ De Soto, Mo.; University of Tennessee College of Medicine, Memphis, 1931; member of the American Academy of General Practice; formerly associated with the Indian Service; veteran of World War II; died July 4, aged 53.

Infield, Gerald Lee ⊕ Northfield, N. J.; Hahnemann Medical College and Hospital, Philadelphia, 1933; health officer; since 1948 mayor; veteran of World War II; medical director of the Atlantic County Hospital for Mental Diseases; died in Atlantic City July 31, aged 51, of congestive heart failure.

Ivanov, Christine Jan, Milwaukee; Marquette University School of Medicine, Milwaukee, 1953; served a residency at the Milwaukee County Hospital for Mental Diseases at Wauwatosa; died July 31, aged 43, of pulmonary embolism following thrombophlebitis of left lower extremity.

Keenan, Maurice Edward, Circle, Mont.; University of Colorado School of Medicine, Denver, 1942; veteran of World War II; died July 16, aged 41, of coronary thrombosis.

Klar, Jacob Joseph ⊕ Springfield, Mass.; College of Physicians and Surgeons, Boston, 1935; died in the Wesson Memorial Hospital Aug. 3, aged 55, of coronary thrombosis.

Kroener, William Frederick Sr., Pebble Beach, Calif.; Rush Medical College, Chicago, 1925; certified by the National Board of Medical Examiners; an associate member of the American Medical Association; veteran of World War I; past president of the Whittier Kiwanis Club and the high school board of Whittier; died in the Peninsula Community Hospital, Carmel, July 16, aged 66, of arteriosclerosis.

Lieberman, Louis James ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1922; veteran of World War II; associated with Mount Sinai, Polyclinic and Woman's hospitals; died July 26, aged 59, of a heart attack.

Lipkin, Harry ⊕ New York City; College of Physicians and Surgeons, Baltimore, 1914; died July 20, aged 66, of carcinoma of the left superior maxillary antrum.

Lurting, Clarence Wilbur ⊕ Pittsburgh; College of Physicians and Surgeons, Baltimore, 1903; on the staff of St. John's General Hospital; died in the Allegheny General Hospital July 22, aged 82, of coronary occlusion.

Lynch, Daniel Webster, Miami, Fla.; Northwestern University Medical School, Chicago, 1905; veteran of World War I; died June 6, aged 78, of pulmonary embolism.

McCurdey, Neil Augustus, Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1896; died May 17, aged 85, of acute coronary insufficiency.

McMann, William Henry ⊕ Boston; Harvard Medical School, Boston, 1900; died in the Carney Hospital May 21, aged 84, of cerebral hemorrhage.

McNulty, John Benjamin ⊕ Memphis, Tenn.; Washington University School of Medicine, St. Louis, 1909; served on the staff of St. Joseph Hospital; died July 18, aged 78.

Mackin, M. Charles ⊕ Des Moines, Iowa; Baltimore Medical College, 1891; Chicago Homeopathic Medical College, 1893; served as superintendent of the

Mount Pleasant (Iowa) State Hospital; died in St. Bernard's Hospital, Council Bluff, July 18, aged 91, of cerebral hemorrhage.

Malloy, Henry Darius, Winston-Salem, N. C.; Leonard Medical School, Raleigh, 1910; honorary staff member of Kate Bitting Reynolds Memorial Hospital; died July 28, aged 72.

Marble, Perley Leonidas ⊕ Liscomb, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1899; Hahnemann Medical College and Hospital of Philadelphia, 1906; on the staff of the Evangelical Hospital, Marshalltown, where he died June 19, aged 85, of coronary disease.

Marcus, Samuel Jerome, Pittsburgh; University of Pittsburgh School of Medicine, 1909; an associate member of the American Medical Association; died in the Mercy Hospital July 25, aged 70.

Mayer, Benjamin Harrison ⊕ Ellsworth, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1911; member of the American Society of Anesthesiologists; veteran of World War I; died July 17, aged 69.

Messer, George Frederick, Milwaukee; Kansas City (Mo.) Medical College, 1892; died July 2, aged 86.

Mikesch, William Henry ⊕ South Bend, Ind.; St. Louis University School of Medicine, 1913; for six years deputy county coroner; veteran of World War I; died in St. Joseph's Hospital June 25, aged 74, of cerebral vascular thrombosis.

Mitchell, Paul Hayne, Ahoskie, N. C.; University College of Medicine, Richmond, 1907; on the staff of the Ranoke-Chowan Hospital, where he died July 24, aged 71, of cerebral hemorrhage.

Moore, George W. ⊕ Bay City, Mich.; Milwaukee Medical College, 1898; past-president of the Bay County Medical Society; for many years health officer of Bay City; on the emeritus staffs, Mercy and General hospitals; died July 15, aged 89, of cerebral thrombosis.

Moore, Jesse McGough, Princeton, Ky.; Hospital College of Medicine, Louisville, 1901; an associate member of the American Medical Association; past-president of the Caldwell County Medical Society; on the staff of the Caldwell County War Memorial Hospital; for many years surgeon for the Illinois Central Railroad; died July 22, aged 81, of chronic myocarditis and arteriosclerosis.

Moore, Joseph Leslie, Brooklyn; University of Pennsylvania Department of Medicine, Philadelphia, 1905; an associate member of the American Medical Association; served on the faculty of the Long Island College of Medicine; veteran of World War I; during World War II a Selective Service examiner; consultant in medicine at the Brooklyn Hospital, where he died July 18, aged 80, of gastric ulcer and peritonitis.

Mueller, Clive Paul, Lieut. Col., U. S. Army, retired, San Antonio, Texas; Northwestern University Medical School, Chicago, 1916; service member of the American Medical Association; veteran of World War I; entered the medical corps of the U. S. Army in 1918 and retired July 1937; died May 30, aged 68, of fracture of the hip and Parkinson's disease.

Myers, Henry F. ⊕ Lancaster, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; formerly member of the city board of education; for many years on the staff of the Rossmere Sanatorium; died July 20, aged 87, of cerebral arteriosclerosis.

Nark, John Aloysius, Philadelphia; Temple University School of Medicine, Philadelphia, 1927; staff member, St. Mary's Hospital; died July 27, aged 55, of carcinoma of the liver.

Newbury, Nelson Edwards, Atlantic City, N. J.; New York University Medical College, New York City, 1897; died in Atlantic City Hospital July 20, aged 82, of uremia and arteriosclerotic heart disease.

Niederwimer, John Stevens, St. Louis; St. Louis University School of Medicine, 1943; interned at St. Louis County Hospital in Clayton, where he served a residency; served a residency at the Robert Koch Hospital in Koch, Mo.; died July 14, aged 38.

Notkins, Louis Adolph, New Haven, Conn.; Yale University School of Medicine, New Haven, 1903; served on the faculty of his alma mater; veteran of World War I; neurologist consultant for the Veterans Administration; died in the Gaylord Farm, Wallingford, July 21, aged 81.

Nulton, Ida May ⊕ Lancaster, Mo.; Keokuk (Iowa) Medical College, 1898; died in St. Joseph's Hospital, Centerville, Iowa, July 13, aged 91, of uremia.

O'Bar, Oliver, Fort Lauderdale, Fla.; Medical Department of Tulane University of Louisiana, New Orleans, 1899; for many years practiced in St. Louis; died July 25, aged 82, of cerebral hemorrhage.

O'Neill, Edward Daniel, Sacramento, Calif.; Louisville (Ky.) and Hospital Medical College, 1908; veteran of World War I; died in the Mercy Hospital July 18, aged 79, of cerebral thrombosis.

Osborn, Alfred Shaffer ⊕ McAllen, Texas; University of Texas School of Medicine, Galveston, 1934; past-president and secretary of the Hidalgo-Starr Counties Medical Society; on the staff of the McAllen Municipal Hospital; accidentally electrocuted July 7, aged 45.

Pennington, Henry Z., Eldorado, Texas (licensed in Texas, under the Act of 1907); died in Memorial Hospital, San Angelo, July 23, aged 90, of carcinoma of the prostate and arteriosclerotic heart disease.

Porterfield, William Lowrie ⊕ McClure, Ill.; Rush Medical College, Chicago, 1902; for many years practiced in Chicago, where he was on the faculty of Loyola University School of Medicine and on the staff of St. Bernard Hospital; died in Baltimore July 20, aged 77, of bronchopneumonia and prostatic adenocarcinoma with metastases.

Price, Alfred Stirgus ⊕ Des Moines, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; veteran of the Spanish-American War and World War I; served as chairman of the Polk County Sanitary Commission and county physician; on the staffs of Mercy Hospital and Iowa Methodist Hospital where he died July 18, aged 77.

Price, William Harrison, Shelter Island Heights, N. Y.; Pulte Medical College, Homeopathic, Cincinnati, 1903; for many years practiced in Brooklyn, where he was on the staffs of the Prospect Heights and Peck Memorial hospitals; died July 19, aged 80, of uremia.

Ramage, Chesney Macauley, Fairmont, W. Va.; Johns Hopkins University School of Medicine, Baltimore, 1910; an associate member of the American Medical Association; fellow of the American College of Surgeons; during World War I medical member of the Fairmont draft board; formerly superintendent of the Fairmont Emergency Hospital; on the staff of the Fairmont General Hospital; died July 12, aged 73, of coronary thrombosis.

Rathman, Omer Charles ⊕ Billings, Mont.; University of Michigan Medical School, Ann Arbor, 1926; fellow of the American College of Surgeons; veteran of World War II; on the staffs of the Billings Deaconess and St. Vincent's hospitals; died July 12, aged 55, of coronary occlusion.

Raynolds, Elmer L. ⊕ Lincoln, Neb.; Eclectic Medical University, Kansas City, Mo., 1901; Kansas City (Mo.) College of Medicine and Surgery, 1916; also a pharmacist, member of the Kansas Medical Society; for many years practiced in Mankato, Kan.; served as health officer of Jewell County, Kan.; died July 28, aged 88, of cerebral hemorrhage.

Rees, Kendall Brooks, Coldwater, Mich.; Detroit College of Medicine, 1912; on the staff of the Coldwater State Home and Training School; died in the Butterworth Hospital, Grand Rapids, June 20, aged 72, of carcinoma.

Remillard, Joseph Laury, Rouses Point, N. Y.; School of Medicine and Surgery of Montreal, Que., Canada, 1897; formerly associated with the U. S. Public Health Service and served as health officer for the village of Rouses Point; died May 22, aged 84, of pneumonia.

Richman, Barash ⊕ Chicago; Chicago Medical School, 1930; field health officer for the Chicago Board of Health; served on the Garfield Park Community Hospital; died in South Haven, Mich., Aug. 3, aged 68, of cerebral hemorrhage.

Samuels, John Goodwin ⊕ Hickman, Ky.; University of Tennessee College of Medicine, Memphis, 1934; member of the American Academy of General Practice and the Industrial Medical Association; president of the Fulton County Medical Society; vice-president of the medical staff, Obion County General Hospital, Union City, Tenn.; died July 14, aged 47, of coronary thrombosis.

Savedoff, William M. ⊕ New York City; Friedrich–Wilhelms–Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1914; associated with Morrisania, and Flower and Fifth Avenue hospitals and the Bronx Hospital, where he died July 23, aged 70, of myocarditis.

Schaefer, Otto ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1894; fellow of the American College of Surgeons; died in Leesburg, Fla., July 1, aged 89, of heart disease.

Scheffer, Carl Julius, West Palm Beach, Fla.; University of Pittsburgh School of Medicine, 1912; died June 14, aged 72, of coronary thrombosis.

Schwab, Frederick, Cedar Rapids, Iowa; Drake University College of Medicine, Des Moines, 1906; died July 7, aged 82, of congestive heart failure.

Sharon, Isaac Paul ⊕ Middlebury, Vt.; University of Vermont College of Medicine, Burlington, 1909; on the staff of the Porter Memorial Hospital; died July 17, aged 77, of congestive cardiac failure.

Shaw, Arthur John, Boston; Harvard Medical School, Boston, 1894; served on the staffs of the St. Elizabeth's Hospital, Massachusetts Eye and Ear Infirmary, and the Children's Medical Center; died in Hull, Mass., July 18, aged 85, of cancer.

Shirley, Carl Wilson ⊕ Houston, Texas; University of Texas School of Medicine, Galveston, 1925; served on the faculty of the Baylor University College of Medicine; veteran of World War II; on the staffs of the Memorial and Hermann hospitals; died July 25, aged 59, of coronary occlusion.

Sidener, Thomas Taylor ⊕ Lima, Ohio; Eclectic Medical Institute, Cincinnati, 1906; died in the Lima Memorial Hospital May 23, aged 90.

Sierakowski, Chester Steven, McKees Rocks, Pa.; University of Pittsburgh School of Medicine, 1910; died in the Presbyterian Hospital, Pittsburgh, June 29, aged 69, of cancer.

Smith, Jesse T., Gamaliel, Ky.; University of Tennessee Medical Department, Nashville, 1895; a member of the county board of health; veteran of World War I; died June 23, aged 90.

Spengler, Frank B., Baldwinsville, N. Y.; Syracuse University College of Medicine, 1906; an associate member of the American Medical Association; served as school physician; died July 16, aged 75, of heart disease.

Sprague, Buell H. ⊕ Los Angeles; Sioux City (Iowa) College of Medicine, 1908; member of the American Academy of General Practice; fellow of the American College of Surgeons; in 1918 member of the House of Delegates of the American Medical Association; on the staffs of St. Joseph's Hospital in Burbank, Calif., and the Hollywood Presbyterian Hospital; died July 14, aged 71, of coronary disease.

Steinfuehrer, Gotthold, Chicago; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1921; died in Vermontville, Mich., June 28, aged 70, of pneumonia and heart disease.

Stone, John Boyd ⊕ Churchville, Va.; University of Virginia Department of Medicine, Charlottesville, 1912; died July 20, aged 71, of coronary occlusion.

Swenson, Leonard Carl ⊕ Freeport, N. Y.; Vanderbilt University School of Medicine, Nashville, Tenn., 1939; died June 12, aged 42, of pulmonary fibrosis and hypertension secondary to Marie–Strümpell's arthritis.

Thomas, George Elwin ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; member of the American Academy of General Practice; died in the Asbury Hospital June 10, aged 80.

Thomas, Merrick Dowdell ⊕ Miami, Fla.; Columbia University College of Physicians and Surgeons, New York City, 1904; died in the Doctors Hospital July 9, aged 80, of pneumonia.

Trigg, Franklin Elem ⊕ Guthrie, Okla.; College of Physicians and Surgeons, Keokuk, Iowa, 1897; died in the Benedictine Heights Hospital June 15, aged 84, of cirrhosis of the liver.

Turman, George Fugett, Missoula, Mont.; University College of Medicine, Richmond, 1905; an associate member of the American Medical Association; past-president of the Montana Department of Public Health; on the staff of St. Patrick Hospital, where he died July 12, aged 74, of carcinoma of the prostate.

Turner, Clifton Sherwood ⊕ Peoria, Ill.; University of Cincinnati College of Medicine, 1920; past-president of the Peoria County Medical Society; member and past-president of the staff, Methodist Hospital; died July 9, aged 62, of arteriosclerotic heart disease.

Turner, Wylie Erasmus Jr. ⊕ Piggott, Ark.; University of Tennessee School of Medicine, Memphis, 1939; member of the American Academy of General Practice; served during World War II; a member of the staff of Piggott Hospital; died July 9, aged 43.

Veech, Annie S., Louisville, Ky.; Woman's Medical College of Pennsylvania, Philadelphia, 1909; in June, 1956, received the achievement award of the alumnae association of her alma mater; first director of the Bureau of Maternal and Child Hygiene in Louisville; died in the Pee Wee Valley Hospital July 10, aged 86.

Wasilewski, Joseph Thomas ⊕ Coatesville, Pa.; Temple University School of Medicine, Philadelphia, 1928; associated with the Veterans Administration Hospital; died in the Temple University Hospital, Philadelphia, June 27, aged 55.

Webb, Enoch Palmer ⊕ Beaver Dam, Wis.; Rush Medical College, Chicago, 1897; died in the Lutheran Hospital June 4, aged 86.

Weber, William Donald ⊕ Cleveland; Duke University School of Medicine, Durham, N. C., 1945; certified by the National Board of Medical Examiners; veteran of World War II; member of the American Trudeau Society; resident, University Hospitals; died July 15, aged 37, of acute coronary thrombosis.

Whitaker, William Batchelor, Chicago; Rush Medical College, Chicago, 1897; once on the staff of the Mercy Hospital; veteran of World War I; died in the Veterans Administration Research Hospital July 23, aged 82, of cerebral hemorrhage.

Wilson, William Berry, Colonel, U. S. Army, retired, Redlands, Calif.; St. Louis University School of Medicine, 1926; entered the medical corps of the U. S. Army in 1927; veteran of World Wars I and II; retired April 30, 1946; service member of the American Medical Association; died June 14, aged 59, of coronary thrombosis.

Wohrley, Ivan Charles, Newark, Ohio; Electic Medical College, Cincinnati, 1922; veteran of World War I; served as a medical missionary in West China; died in the University Hospital, Columbus, July 5, aged 62, of coronary infarction.

Worthey, William R. ⊕ Call, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1912; past-president of the Jasper–Newton Counties Medical Society; died July 3, aged 82.

FOREIGN LETTERS

BRAZIL

Drugs Acting on Sphincter of Oddi.—In the Hospital das Clinicas of the University of São Paulo, Drs. A. Raia and C. Horta investigated the action of the following drugs on the sphincter of Oddi: iodinated contrast mediums used in cholangiography, morphine, diphenylhydantoin sodium, atropine, antihistaminic drugs, thiopental sodium, curare, and amyl nitrite. A contrast medium in the biliary ducts may cause hypertension in the common bile duct. This is not related to the amount of fluid injected. In some subjects, antihistaminic drugs, such as promethazine hydrochloride, may reverse the effect of the contrast medium. Morphine in a dose of 10 mg. and diphenylhydantoin in a dose of 50 mg. caused hypertension in the biliary tree. Atropine and scopolamine hydrobromide given intravenously do not relax the sphincter of Oddi and do not change the pressure in the biliary ducts. Amyl nitrite relaxes the sphincter of Oddi. Its action is quick but transient. Thiopental, curare, and promethazine do not change the pressure within the biliary tree and may be used in patients with pathological conditions of the biliary tree in which we wish to perform manometry and cholangiography.

Megacolon and Megarectum.—At a meeting of the Brazilian College of Surgeons, Dr. Azael Leitzner reported a series of 20 rectosigmoidectomies (6 by the abdominal route and 14 by the abdominoperineal route). None of the patients had had a previous colostomy. In 18 a megasigmoid and in 2 a megarectum was found. The follow-up period ranged from 16 days to five years. Good functional results were obtained in 17 of the patients. A perirectal abscess developed in one patient, and in six partial disruption of the anastomosis occurred. The abscess was treated by a colostomy. Disruption of the anastomosis in one patient lead to suprapubic fistula, in three to vaginal fistulas (one with rectal stenosis), in one to perineal fistula, and in one to perineal and vaginal fistula. Of these seven patients with complications, spontaneous cure occurred in one, one was to have reoperation but died before this could be done, and in five a colostomy was performed. In these five the fistula closed; the colostomy was taken down in two patients, in two a fistula persisted, and one died of acute peritonitis with congestive heart failure. There was a late death (78 days after the operation) which was not related to the operation (suicide by starvation in a mental patient). Dr. Leitzner believes that previous or simultaneous colostomy would have prevented the death caused by acute peritonitis in the patient with heart failure, although a colostomy does not always prevent disruption of sutures. In spite of this, he advises colostomy only when there are serious complications, and he advocates rectosigmoidectomy in the treatment of megasigmoid and megarectum, although the operation is a major one and serious complications may occur.

CANADA

Radioactive Cobalt Therapy.—The June, 1957, issue of the *Journal of the Canadian Association of Radiologists* is chiefly devoted to radioactive cobalt (Co^{60}). It is over five years since Co^{60} beam therapy units were first used in Canada. A preliminary report from Saskatoon summarizes the treatment by Co^{60} of 942 patients with malignant disease in a total series of 3,957 patients treated by various forms of radiation therapy. Predictions made five years ago that the new compact powerful sources of Co^{60} would not only supplant radium beam therapy but also compete with x-ray machines in the 2 and 3 megavolt region have come true and have even been surpassed. Teletherapy units are now available with smaller sources of Co^{60} of the order of 500 to 600 curies for use at shorter treatment distances, generally 50 cm. focus-skin distance. An editorial draws attention to the fact that the main advantage of Co^{60} irradiation used for teletherapy lies in the treatment of deep-seated lesions that could hardly ever be treated adequately with conventional x-ray therapy. It is not due to any special virtue of Co^{60} radiation but is related to the greater penetrating power and the scattering in a forward direction of such radiation. Excessive tissue reactions can thus be avoided. It is difficult to determine whether Co^{60} will improve the results in treatment of neoplastic diseases over those obtained by conventional 0.2 to 0.3 megavolt radiation. It is suggested, however, that doses of Co^{60} radiation 15 to 20% greater than those of supervoltage x-radiation will be required to induce the same biological effects.

Heredity Counseling Service.—The faculty of medicine of the University of Alberta has established a heredity counseling service which will provide consultation to persons referred to it by physicians.

The items in these letters are contributed by regular correspondents in the various foreign countries.

This service has been set up as a committee composed of the heads of five clinical departments (medicine, obstetrics, pediatrics, preventive medicine, and psychiatry) and a consultant in genetics. Personal consultations with patients and their families may be arranged when necessary. The object of the service is to give a clear picture to laymen of the genetic principles involved in any case of hereditary or familial disease. By clarifying the genetic picture, the counselor will assist the patient in putting his total problem into perspective so that he may arrive at his own conclusions. It is no part of the duty of the service to give advice concerning future reproductive behavior, which involves not only biological but also religious, economic, and other factors. In addition to its value to patients and practitioners, the service hopes to accumulate some data which will advance knowledge in human genetics and help with the education of medical students. The 1957 graduating class of the faculty of medicine of the University of Alberta is the first class which has had a systematic course in human genetics covering such topics as the physical basis of heredity, statistical probability, simple single-factor inheritance, blood group genetics, the interaction of heredity and environment, the effects of ionizing radiation, and the applications of genetic knowledge to man.

Immunology and the Canadian Indian.—Although the increase in the Indian population of Canada is proceeding more rapidly than the increase in the non-Indian group, there is still a relatively high death rate, and an appreciable amount of morbidity is still due to communicable diseases. An intensive immunization program has been carried out for several years by the Indian and Northern Health Services of the Department of National Health and Welfare of Canada. Combined diphtheria, pertussis, and tetanus antigen has been supplied to every tribe; BCG vaccination has been encouraged and T. A. B. vaccine has been given when thought necessary. Nevertheless, the general immunological status of the nomadic Indian tribes is unsatisfactory, and federal public health officials have therefore recently carried out a survey of 797 Indians distributed throughout Canada. The results (*Canadian M. A. J.* 77:211 [Aug. 1] 1957) show that general immunity to diphtheria is good, for, of 770 serums titrated, 722 had greater than the Schick immune level of 0.004 unit of antitoxin per milliliter. Though protection against tetanus was not so prevalent, it is expected that with the increased use of tetanus toxoid this situation will improve rapidly. The effectiveness of protection against pertussis was difficult to judge. There was a low incidence of both O and H agglutinins of Salmonella paratyphi A and Salmonella paratyphi C but a high incidence of O and H agglutinins of Salmonella typhi and Salmonella paratyphi B. It would seem, therefore, that typhoid and paratyphoid type B are highly endemic among the groups studied and that vaccination against these should be more widely applied among all Indians. The immunological study suggested that Brucella abortus infection is of relatively minor concern in Indian populations, but tularemia seems to be endemic in certain areas.

Research Prizes.—A new type of charitable foundation for research into rheumatic and heart disease has been set up by a Toronto philanthropist, Mr. James A. Gairdner, who has provided an initial capital of $500,000 to establish the Gairdner Foundation which will provide prizes totaling up to $50,000 a year as rewards to medical men for major research contributions. This is an unusual type of foundation in that it does not aim to give grants to investigators but merely to reward their successes. Investigators will be free to use the award money as they see fit. There will be two types of awards. A class A award of $25,000 is to be given at least once every four years to an investigator whose work is distinguished in the field of connective tissue diseases or heart disease. International awards of three to five annual prizes of not less than $3,000 and not more than $10,000 are to be given for outstanding accomplishments in the same fields. A board of trustees has been created, and the physicians-in-chief of the University of Toronto teaching hospitals will serve as a medical advisory committee. It is possible that the scope of the awards may be expanded later to other fields, particularly to degenerative diseases.

Perphenazine, a New Tranquilizer.—In the *Canadian Psychiatric Association Journal* (2:104, 1957) Cahn and Lehmann report a study of perphenazine (Trilafon), an amino derivative of chlorphenothiazine with ataraxic properties. They used the drug for 84 female patients, 26 of whom were undergoing a severe acute psychiatric disturbance and the remainder being mostly chronic schizophrenics. The drug was given intramuscularly and by mouth, the intramuscular dosage ranging from 15 to 60 mg. a day and the oral dosage from 8 to 192 mg. a day. Excitement, hyperactivity, talkativeness, and insomnia were controlled to much the same extent as with chlorpromazine. The drug was not effective in patients with endogenous depression. Perphenazine also proved a potent therapeutic agent in patients with chronic psychoses. Clinical results similar to those with chlorpromazine were obtained with about one-sixth of the dose of the latter. The principal differences from chlorpromazine were that perphenazine is less painful on intramuscular injection and has fewer autonomic and allergic side-effects but causes extrapyramidal symptoms more frequently and earlier than does chlorpromazine, though these symptoms are well controlled by various drugs given for Parkinsonism. This study suggested that perphenazine should not be combined with reserpine or given to obese patients. Otherwise it is a useful and safe therapeutic agent in acute and chronic psychiatric disorders.

Chloroquine in Rheumatoid Disease.—The first long-term (four-year) study of continuous daily treatment with chloroquine by mouth for rheumatoid disease was reported by Bagnall (*Canad. M. A. J.* 77:182 [Aug. 1] 1957). The author is enthusiastic about the results which were studied in 125 private patients, most of whom had classic rheumatoid arthritis although 17 had spondylitis and 10 concomitant psoriasis. There was no difficulty in distinguishing the chloroquine-treated group from the placebo-treated group. In general, the results were considered "good" in 70% of the patients, one-half being in remission. Work performance increased in these patients, the sedimentation rate dropped, and the hemoglobin level rose. Most of these successfully treated patients had received chloroquine therapy for more than two years. All types of rheumatoid disease appeared to respond equally well. Half of the 30% of failures were probably due to toxic reactions that seriously affected the ability to take an adequate dosage. The normal dosage was one 250-mg. tablet of the diphosphate daily at bedtime. Minor toxic effects were common, drug dermatitis being the one most significantly restricting treatment. Hydrochloroquine is under trial as a substitute to try to reduce the incidence of these reactions. There was no agranulocytosis, but leukopenia was noted on six occasions. Chloroquine does not begin to show favorable effects for from 1 to 3 months, and maximum benefit may be delayed 6 to 12 months or even more. The author believes that chloroquine comes closest to the ideal for long-term safe control of rheumatoid disease. The mechanism of action is unknown.

DENMARK

Ultrasonic Treatment.—Dr. Hans Graudal, in *Ugeskrift for Læger* for Aug. 1, noted that, while experimental work has thrown much light on the biological action of ultrasound, clinical tests have failed to show clearly which are the accepted indications for such treatment. This treatment should be based on the fact that ultrasound can produce a deep heating of the tissues with a specific distribution of the rise of temperature. The analgesic effects obtained may also be traced to this. In 43 male and 10 female patients given ultrasonic treatment for hematomas arising in many cases from sport injuries, the size of the hematomas ranged from that of a nut to that of a clenched fist, and in some they were diffuse, extending over the anterior surface of the whole of one thigh. There was no need to extend this treatment beyond a week, and, when the patients were classified according to whether they were treated every day or every other day, the disappearance of the hematomas was found to be about twice as rapid in the former as in the latter group. Undesirable side-effects were not observed.

Hemorrhages from Salicylic Acid.—To investigate the rather vague impression that salicylic acid frequently causes gastrointestinal hemorrhages, Dr. Lis Mellemgaard (*Ugeskrift for læger*, July 18, 1957) reported the findings in a series of 124 patients, excluding those in whom the hemorrhage might have been due to gastric ulcer, cancer, or varicose veins. Of these, 18 had taken large quantities of salicylic acid shortly before admission to the hospital. Attention is drawn to a vicious circle. Taking salicylates leads to mucosal bleeding. The ensuing anemia gives rise to headache which in its turn calls for the taking of more salicylates. Again, the anemia so often associated with chronic diseases of the joints may not always be due to them but may be the outcome of taking salicylates. Because occult gastrointestinal hemorrhages are such a drain on the diagnostic resources of radiologists and others, awareness of the dangers of salicylate medication may often prove helpful.

Driving Licenses for Drug Addicts?—In the period 1949-1955, the health authorities had to deal with 15 cases in which traffic accidents or reckless driving had raised the problem of drug addiction. These were comparatively straightforward cases, in that they were not complicated by the intake of alcohol or by other extraneous circumstances. Drug addiction being so often hushed up, these few cases coming into the open present an incomplete picture of the real dimensions of the problem which is ventilated by Dr. Mogens Nimb in *Ugeskrift for læger* for Aug. 1. The physician countersigning an application for a driving license is not required to ask specifically if the applicant is dependent on drugs other than insulin, but he must certify that the applicant is not suffering from any disease calculated to impair his capacity to drive a car. Most physicians interpret this clause as applicable to drug addiction, but some have ignored this particular risk. In several cases, finding some barbiturate in the blood has determined the issue. When a driver suspected of drug addiction happens to be a physician, the case may be complicated by the possible withdrawal of his right to practice medicine as well as his right to drive a car. In one such case the legal authorities refused to withdraw the doctor's driving license on the plea that as his license to practice medicine had not been withdrawn his right to drive could hardly be challenged —an argument that Nimb refuses to endorse. He foresees that traffic regulations may be invoked to help promote the campaign against drug addiction.

from 0.01 to 0.03% of vanadium, which accumulates in the soot. Some oils, such as Venezuelan, deposit on burning a soot containing 45% vanadium as pentoxide, while Middle Eastern oils contain only a trace. Workers enter the boilers to remove soot that collects on the heat exchanges and walls. This is removed by scraping, and, during the process, clouds of soot containing vanadium are inhaled. The initial symptoms of vanadium poisoning, which come on within 30 minutes of exposure to the dust, are rhinorrhea, sneezing, watering of the eyes, sore throat, and retrosternal pain. The late symptoms, which occur within 6 to 24 hours, include tightness across the chest, wheezing, dyspnea, epigastric pain, and depression. There is also a dark green discoloration of the tongue. The symptoms last for a few days after exposure. Vanadium can be detected in the urine. Outbreaks occur on oil-burning ships. The workers develop a chronic bronchitis and emphysema. Vanadium poisoning is prevented by wearing dust respirators, using vacuum cleaners for removing as much of the soot as possible, and washing down walls with water sprays.

Scorpion Stings.—In a letter to the *British Medical Journal* of Aug. 10, Dr. M. McA. Holmes of Sokoto, Nigeria, stated that 65 mg. of emetine hydrochloride in 1 ml. of water injected into an area stung by a scorpion gives immediate relief. Sometimes 0.5 ml. or less is sufficient. The author treated over 30 African and European patients by this method. The expression of relief from pain on their faces was obvious and gratifying. Previously, various brands of local analgesics were found to be useless. The writer treated patients who had received a local analgesic and after two or three hours returned with the agonizing pain, which was relieved permanently by emetine. Scorpion venom is a neurotoxin and emetine a protoplasmic poison. The mechanism of the relief is unknown. The writer makes no claim to having discovered this treatment himself.

Inhalation of Grass Spikes.—Inhalation of grass spikes may result in serious consequences if the spike is barbed, as in the case of barley grass, in which the spicules are firm and sharp, are set at an acute angle to a rigid stem, and do not soften on moistening. The arrangement of the spicules in this and some other grasses causes one-way travel with thoracic movement and drives the point onwards. Godfrey (*Lancet* 2:273, 1957) reports the case of a boy of 9 years who complained of abdominal pain on the right side. Appendicitis was diagnosed and a healthy appendix removed. Shortly afterwards rales were heard on the right side of the chest, and a roentgenogram revealed bronchopneumonia in the base of the right lung, which responded to treatment. Four months later, however, the child was expectorating purulent sputum. After the boy had undergone many admissions to hospital and repeated bronchoscopy and bronchography, lobectomy on the right was done. Section of the excised lung showed a well-preserved inflorescence of barley grass 2 in. long. This had been inhaled two days before the onset of the original abdominal pain. In another case, a girl of 16 months inhaled two grass seeds. Owing to subsequent coughing, retching, and cyanosis, a bronchoscopy was performed and a barbed grass seed removed from the right main bronchus. After two weeks, the radiological signs improved, but 17 days after the original incident the cough recurred, a roentgenogram revealed a slight opacity in the base of the right lung, and the child had a remittant fever. A hot tender fluctuant swelling 2 in. in diameter suddenly appeared to the right of the fourth lumbar vertebra. When incised, it discharged pus containing Escherichia coli for a few weeks. Seven weeks after it had been inhaled, a spike of barley grass more than 2 in. long was removed from the sinus. Removal of the spike produced a fit of coughing, and iodized oil injected into the sinus was traced as far as the diaphragm. The ratchet-like action drove the spike through the lung, diaphragm, and lumbar muscles and out through the skin. It is not known whether permanent lung damage occurred.

Welfare Foods.—A subcommittee under Lord Cohen has made recommendations on the distribution of "welfare foods" (Report of the Joint Subcommittee on Welfare Foods, Her Majesty's Stationery Office, 1957). Orange juice and cod liver oil are free for young children. The subcommittee recommends that the scheme be continued but that orange juice should no longer be given to children over the age of 2 years, because scurvy is almost unknown in older children. Some children have been given enormous doses of vitamin D, e. g., 35,000 I.U. daily, by misguided mothers who give them excessive quantities of cod liver oil as well as foods and proprietary preparations fortified by vitamin D. They thus run a risk of hypercalcemia. As rickets is still seen, the subcommittee considers that cod liver oil supplements should still be issued, but it suggests that the amount of vitamin D be reduced. The new levels for food fortification with vitamin D are: (1) national cod liver oil, average 100 I.U. per Gm. (formerly 200 I.U. minimum); (2) national dried milk, average 90 to 100 I.U. per ounce of powder (formerly 280 I.U. minimum); and (3) infant cereals, average 300 I.U. per ounce of dry cereal (formerly 1,000 I.U. minimum). These levels take into consideration the suggestion of Medical Research Council Conference on Hypercalcemia, which considered a daily intake of 400 I.U. of vitamin D throughout infancy sufficient. The subcommittee hopes that manufacturers of infant foods will cooperate to insure that they do not upset the balance by excessive fortification of these foods with vitamin D.

CORRESPONDENCE

HEART BLOOD VS. FEMORAL VEIN BLOOD FOR POSTMORTEM ALCOHOL DETERMINATIONS

To the Editor:—In the paper by Turkel and Gifford, "Erroneous Blood Alcohol Findings at Autopsy," which appeared in the July 6, 1957, issue of The Journal, the authors reported analyses for alcohol conducted on heart blood and femoral vein blood taken from 51 alcoholic cadavers during autopsies performed 3 to 72 hours after death. In 16 of the cases the alcohol level in the femoral blood exceeded the heart level, the ratio being 0.95 to 0.99 in 13, 0.85 in 2, and 0.81 in one. With the remaining 36 bodies, the ratio of heart blood sample to femoral vein blood sample exceeded 1.00 and was above 1.10 in 11 (1.11 to 1.54, average 1.23). Turkel and Gifford ascribe these high ratios to postmortem diffusion of unabsorbed alcohol from the stomach to the region of the heart.

Another factor, apparently overlooked by these authors, may have been the cause of some of the high alcohol ratios It is the normal lag in the alcohol level of the venous return from a limb during active absorption of orally administered alcohol. This lag was first reported by Haggard and Greenberg in 1934 (*J. Pharmacol. & Exper. Therap.* 52:150-166 [Oct.] 1934), on the basis of tests with one dog This phenomenon was subsequently confirmed by us in a large number of dog experiments (Harger, Hulpieu, and Cole: *Fed. Proc.* 4:123 [March] 1945, Forney, Hulpieu, and Harger: abstracted, *J Pharmacol. & Exper. Therap.* 98:8 [Jan.] 1950), although our figures for the magnitude and duration of the lag were lower than those of Haggard and Greenberg Our dogs received, by stomach tube, 1 to 4 Gm. of alcohol per kilogram in a concentration of 24% by volume. Samples of heart blood and saphenous vein blood were taken simultaneously from the living animals at various time intervals. A summary of our findings is represented in the table

*Summary of Findings in Samples of Heart and Saphenous Vein Blood**

No of Animals	Time Interval	Ratio of Heart to Saphenous Blood Alcohol	
		Range	Av
13	10 min	(1)0.98, (12)1.22-1.93	(13)1.41
17	15 min	1.04-1.49	1.20
17	30 min	0.98-1.27	1.10
17	1 hr	0.90-1.15	1.01
17	2 hr	0.91-1.03	0.99
17	3 hr	0.96-1.13	1.01

* Femoral blood samples taken at 15 and 30 minutes gave results which were almost identical with those from saphenous blood

More recently Forney, Baker, and I (*Quart. J. Stud. Alcohol* 17:1-18 [March] 1956) have demonstrated this type of lag in the alcohol level of cubital vein blood of humans, as compared with the level of their fingertip capillary blood. Thirty-four such pairs of blood were taken within 70 minutes after the last drink. The ratios of capillary to venous alcohol of 13 of these ranged from 1.11 to 1.22, with an average of 1.15. The alcohol level of capillary blood is always very close to that of arterial blood (Haggard and Greenberg, *loc. cit.*).

In a previous study by Gifford and Turkel (*J. A. M. A.* 161:866-868 [June 30] 1956), they introduced 3 to 6 fluid ounces of straight whiskey into the stomachs of 11 nonalcoholic cadavers. After intervals of 10.5 to 24 hours they found alcohol in the heart blood, ranging from less than 0.02% in four cases to 0.106% in one body where death was due to peritonitis. Blood from the femoral vein contained no alcohol, except for a faint trace in one case. These results are in agreement with earlier studies of O. Huber (*Deutsch Ztschr. ges. gerichtl. Med.* 37:128-135, 1943) and by Bowden and McCallum (*M. J. Australia* 2:76-81 [July 2] 1949). However, the conditions employed in these three investigations are very drastic, since the concentration of alcohol introduced into the cadaver stomach was much higher than one would usually find in the stomach of a heavy drinker 10 to 15 minutes after his last drink, because the drop in the alcohol level in the living stomach is exceedingly rapid. (On this point see The Pharmacology of Alcohol, by Hulpieu and me in "Alcoholism" [edited by G. N. Thompson, Springfield, Ill., Charles C Thomas, Publisher, 1956, chap. 2, pp. 122-127]).

Since the alcohol level of the brain always parallels that of arterial blood, but not of that return blood from a limb during active absorption (Harger: *J. Forensic Sc.* 1:27-38 [April] 1956), it may be that the "error" in cadaver blood is in femoral vein blood and not in heart blood This point can be settled by experiments with animals which are quickly killed after receiving alcohol orally, where samples of femoral vein and heart blood are taken immediately after death and again after the lapse of 12 to 24 hours. The same type of study should also be made in cases of sudden death in humans who have been drinking heavily shortly before death.

Indiana University School of Medicine
Indianapolis.

BLOOD ALCOHOL FINDINGS AT AUTOPSY

To the Editor:—The paper "Erroneous Blood Alcohol Findings at Autopsy" by Turkel and Gifford (*J. A. M. A.* 164:1077-1079 [July 6] 1957) raises several interesting medicolegal questions. 1. It points up a fallacy of interpretation which is commonly made by attorneys but which is less frequently made by medical scientists, that the blood alcohol level which indicates intoxication is 0.15%. In the courtroom there is a tendency on the part of attorneys to believe that all persons having 0.15% or more alcohol in their blood are drunk, whereas those having 0.14% or less are sober. The report of the A. M. A. Committee to Study Problems of Motor Vehicle Accidents (Organization Section, *J. A. M. A.* 124:1290 [April 29] 1944) establishes a "floor" value of 0.05% in the blood below which it may be fairly presumed that no one is under the influence of alcohol, and a "ceiling" value of 0.15% above which persons may be presumed to be under the influence. Of the intermediate questionable zone they stated that in this "liberal wide zone: alcohol influence *usually* is present, but courts of law are advised to consider the behavior of the individual and circumstances leading to the arrest in making their decision" (italics added). More recently the Committee on Medical Aspects of Automobile Injuries and Deaths recommended that, in the interest of public safety, this "ceiling" value of 0.15% be reduced to 0.05% (Organization Section, *J. A. M. A.* 163:1149-1150 [March 30] 1957). For Turkel and Gifford to imply that a finding of 0.11% alcohol in the blood establishes sobriety is misleading.

2. A second source of confusion stems from the unreal and meaningless use of blood analysis values reported to the third significant figure. To calculate one's analyses to the thousandth of 1% when the admitted analytical error is ±5% gives a false impression of accuracy. It should be pointed out that in a factor such as alcohol influence which, in man, varies from 0.05 to 0.15% alcohol content of blood, variations of 0.01 or 0.02% have little clinical significance.

3. The generally accepted yardstick for the biochemical estimation of intoxication is the alcohol content of whole blood. The specimens of "heart blood" which Drs. Turkel and Gifford obtained at autopsy were not whole blood but rather blood pooled in the pericardial sac. This consisted of bloody serous fluid contaminated by pericardial fluid. Since it is well established that the concentration of alcohol in serum is 10 to 20% higher than that of whole blood, variations in the relative proportion of serum and cellular components in an autopsy specimen of blood may give rise to wide variations in its alcohol content. Pericardial fluid, as shown by Gifford and Turkel (*J. A. M. A.* 161:866-868 [June 30] 1956) is highly susceptible to contamination by diffusion from alcohol-rich stomach contents. To obtain uncontaminated heart blood at autopsy is comparatively easy. When one severs the large vessels of the heart, the bloody contents (including clots) may be pressed out and caught in a 4-oz. wide-mouth jar. A specimen so obtained gives a good approximation of whole blood in the heart.

4. The question of postmortem diffusion of alcohol is not new (see Blutalkohol by H. Elbel and F. Schleyer [ed. 2, Stuttgart, Georg, Thieme Verlag, 1956, p. 126] for a review of the European literature since 1935). That the resulting errors are more apparent than real is borne out by an analysis of the 75 cases reported by Turkel and Gifford. Of these, 24 were entirely sober; 5 had been drinking alcoholic liquor but could be fairly presumed not to be under the influence of alcohol; 17 fell into the questionable zone between 0.05 and 0.15%; and 28 could be fairly presumed to be under the influence of intoxicants. In no case would an erroneous diagnosis have been made by relying on "heart blood" values rather than those obtained from femoral blood. In the most aberrant value reported by Turkel and Gifford in which the heart blood concentration was found to be 0.09% higher than that of the femoral blood, the victim was not simply under the influence; he was drunk (0.35%). The authors' argument could have been made much more convincing had they analyzed the stomach contents in their patients in order to establish a direct basis for assuming that the observed disparity was due to diffusion and not to an unduly high proportion of serum in the heart blood or its contamination by pericardial fluid.

HYPOTHYROIDISM

To the Editor:—As a midwestern physician with an interest in metabolic disease, I am somewhat concerned by certain views expressed in a recent paper entitled "Hypothyroidism" (*J. A. M. A.* 165:121-124 [Sept. 14] 1957). The author's assertions that hypothyroidism is the most frequent affliction in the Midwest, that exophthalmic goiter may be induced by the administration of exogenous thyroid, and that the most frequent cause of daily headache is hypothyroidism seem open to question. While the insidious onset of myxedema frequently impedes its early diagnosis, the ill-advised use of thyroid substances seems much more prevalent than the disease. There are well-defined criteria for the diagnosis of deficient thyroid function, and thyroid therapy for vague or ill-defined syndromes should be discouraged.

THE LEISURE CORNER

LET'S GO BOWLING

Like most pastimes, the game of bowling has kept pace with revolutionary processes. In the beginning, bowling was a crude recreation played with primitive equipment in any available open space. But, as the sport evolved it was transformed from a childish game to that of a sport with universal appeal for people of all manners and ages. Today, many physicians recommend bowling to patients, not only because of the amusement factor but because it is a builder of well-being, for it exercises unused muscles of the body and can be played the year round.

At one time or another, everyone has the urge to throw or roll an object. Relics of the Stone Age depict stones being rolled or thrown at other stones; indeed, the ancient game known as duck-on-the-rock is a forerunner of bowling. History, furthermore, informs us that bowling actually is an ancient and royal sport, engaged in at one time only by members of the aristocracy. During the reign of Henry IV, bowling became so popular in England that public alleys were built in connection with dining establishments.

While skittles, Dutch-rubbers, cloish, and skayles have all had their part in the development of modern bowling, the most closely allied is the game nine-pins. This game originated with the Dutch and was brought by them to American shores in 1623. At that time, nine-pins was bowled on alley beds made of clay. Later on, a single board about 12 in. wide was used as an alley bed; pins were set up in sets of three and in rows of three on a board platform 36 to 48 in. square. The game of nine-pins gained great popularity for many years. As a result of an enactment of a law against the game, a 10th pin was eventually added, changing the set-up from a diamond shape to a triangular system.

Pins used at different periods ranged from 3 to 15 in number and consisted of a variety of shapes, sizes, and arrangements. Alleys or court beds consisted of lawn, clay, slate, and planks 12 in. or more in width and ranging from 20 to 100 ft. in length. One to three balls were permitted in each frame at various stages in the evolution of bowling.

It is interesting to note that Sir Francis Drake was an ardent bowler. One story has it that in 1588, while participating in a bowling match, the famous English sea hero was notified that the Spanish Armada had arrived in the English Channel. Not having vanquished his bowling opponent, he delayed going to sea against the enemy flotilla until the bowling match was won.

On Sept. 9, 1895, the American Bowling Congress was established to promote and elevate the game. The congress formulated a uniform set of playing rules and established regulations to cover the building of bowling alleys and equipment. As a result, bowling today is effectively regulated by the American Bowling Congress and the pastime is considered by many to be the best organized of all sports. The laws of the congress are formulated and distributed at an annual convention held during the tournament season.

Bowling is an intricate skill that requires as much technical aptitude as any other game. The object of bowling is to topple the greatest number of pins with the least number of balls rolled. After bowling a few times, the beginner discovers the fascination of hearing a ball crash into pins and seeing them fall. Bowling should not be regarded as a game of brute strength; it does not consist merely of throwing a ball with all the speed that can be mustered, trusting to luck that the pins will topple. When skillful players compete they know precisely how to achieve desired results. The occasions they fail can often be attributed to faulty footwork, to the time they half-drop a ball, to failure to place it properly on the alley, and to failure to roll the ball at a correct and proper angle. Too much speed or errors in judgment are disadvantages to mar a bowling score. Paradoxically, a bowler with a small stature often appears to have advantages over his heavier, more sturdily built competitor.

A foremost consideration in bowling is the selection of a ball. A ball should fit the hand of an individual just as comfortably as a pair of shoes should fit the feet. Finger holes should be spaced so that it is unnecessary to stretch the hand unnaturally. Neither should finger holes be so close as to make one strain the hand in order to hold the ball firmly and with ease. Unless a ball fits the hand comfortably, it is almost impossible to deliver it easily and properly.

After a properly fitted ball has been selected, the next step is to perfect the stride to the foul line. An experienced bowler can usually give appropriate instructions for the adoption of a comfortable style without straining. In a very short time, this will become a natural part of one's bowling habits. The first or strike ball is most important, and great effort should be made to see that if no strike is accomplished, as large a number of pins as possible are obtained, making the remaining spare shots relatively simple. The weight of pins can generally be determined by watching their action when the ball comes in contact with them. When they are light, you will notice that they jump or raise as they are hit. Consequently, light pins require a slower ball. Heavy pins, on the other hand, call for a trifle more speed. Pins of mixed weight are difficult to knock down because the action of the ball varies.

Keeping score is an important part of the game and it provides a part of the anticipation in the sport. When one becomes familiar with terms such as spare, railroad, cherry pick, tapping, and crossing over mean, interest in the game is enhanced. In general, a game consists of 10 frames. One counts only the actual number of pins knocked down if 10 pins are not made with two balls in the same frame. If a spare is made, a count of 10 plus the number of pins knocked down with the next ball gives a total for a frame. The results of each succeeding frame are continually added until 10 frames have been bowled.

Every physician who has ever taken up bowling knows how enjoyable it can be. While proficiency is a common goal of all bowlers, the score is not necessarily related to the amount of pleasure to be derived. Fellow bowlers invariably laugh when you laugh, moan when you moan, and thrill with you at a successful shot. Bowling makes you feel "you're the tops." You enjoy a leading role, the stage is yours, and all eyes rest upon you. And if there is the slightest bit of "ham" in a bowler, he will derive considerable joy in putting on a humorous act.

Not everyone can be an ace bowler. Most of our country's 20 million bowlers average under 170. Whatever the score, the same full measure of pleasure and physical exhilaration from bowling can be had by all participants. In the final analysis, it is precisely these merits that give the sport its rich flavor. There is more to the game than just felling shiny hunks of maple. There are specific rules to be followed; to violate them is to violate good manners in bowling, and this is a cardinal sin in the sport.

Finally, a few terse "don'ts" about bowling should you decide to take up the game. Do not interfere in any way with a bowler who has taken his stance on an adjoining lane. Do not start when he starts and race him to the foul line. If he is ready to deliver his ball, give him the go-ahead signal and stand completely clear. Do not let bad breaks get you down. As a physician, you frequently utter encouraging advice to your patients. When you go bowling, remember to apply it to yourself. So, roll out the ball and have a good bowling laugh!

MEDICAL FILM REVIEWS

Time and Two Women: 16 mm., color, sound, showing time 18 minutes. Produced in 1957 by Audio Productions, New York, for and procurable on loan from the American Cancer Society, 521 W. 57th St., New York 19.

This film alerts women to the urgency of early detection of uterine cancer and explains the uterine cancer cell examination (the "Pap" smear). It is narrated by Dr. Joe V. Meigs of Boston, who tells the stories of two women who had cancer of the uterus: one who ignored warning signals and saw her doctor too late, and the other whose early cervical cancer was detected in the course of a periodic checkup. The growth of cancer is shown by animated diagrams; and a photomicrograph of a cervical smear, with normal and malignant cells, identifies for the viewer how the pathologist can suspect the presence of cancer by noting cells' structural abnormalities. Details of the routine examination are explained, emphasizing that the patient experiences no discomfort during the procedure. Since the second patient's laboratory report indicated the presence of abnormal cells, she returned the following day, when several small tissue specimens were removed from the cervix. These enabled the pathologist to make a positive diagnosis of cancer. After treatment, she reported for follow-up examination, including smears, for five years, during which she showed no further evidence of disease. The film is concluded with an appeal for women to go to their family physicians once a year for a pelvic examination even though they have no symptoms.

This film should be considered as part of a broad program of professional and public education. At each showing, a doctor should be present to answer questions from the audience; slides of key materials in the film are supplied for projection during the discussion period. At the present time there are not enough trained professional assistants for the pathologists in analyzing specimens taken for cell examination; therefore, the film should be shown only in those areas where the county medical society approves and where pathologists are prepared to read smears. This is an excellent film, clear-cut, pertinent, concise, and very illuminating. The participants perform their parts exceptionally well and the photography is excellent. It is recommended for showing to all women in those areas where facilities for cancer cell examination are available.

ILLUSTRATED FILM REVIEWS

Illustrated reviews of current films will appear when possible as a regular feature in The Journal. *They will consist of an introduction by the author followed by a pictorial digest of actual frame enlargements selected as key points of the film.*

Ralph P. Creer, *Director*
Motion Pictures and Medical Television
Council on Scientific Assembly.

TIME AND TWO WOMEN

Joe V. Meigs, M.D., Boston

Seeking to motivate women to adopt the lifesaving habit of health checkups, this film was released as a part of a broad education program which will be undertaken in communities where technical facilities are available for interpreting vaginal smears, and where the county medical societies approve use of the film. The uterine cancer cell examination, the "Pap" smear, is explained in an effort to alert women to the urgency of early detection of uterine cancer.

The film deals with diagnosis of cancer of the uterus with special emphasis on cytology and dramatizes the fate of two women: one who ignored warning signals and saw her doctor too late and the other whose early cervical cancer was detected in the course of a periodic checkup. The written review of this film appears on page 728 of this issue.

Fig. 1.—Dr. Joe V. Meigs, consulting visiting gynecologist, Vincent Memorial Hospital, Massachusetts General Hospital, Boston, makes the point that 16,000 women die needlessly each year of uterine cancer.

Fig. 2.—First patient confesses that she has not had a checkup in over 19 years. She consults the doctor after months of delay. First symptom was ignored. She now has bleeding, loss of weight, and pains in legs and back.

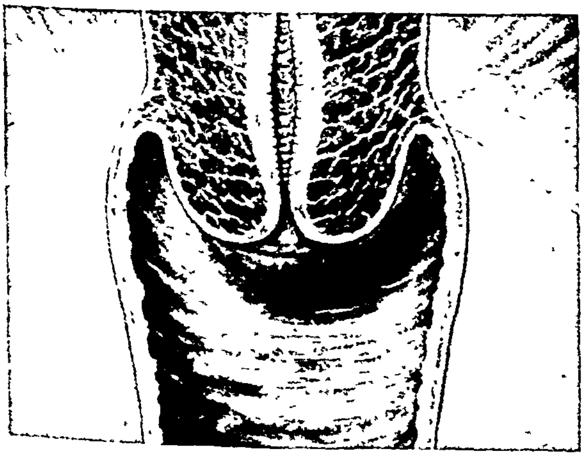

Fig. 3.—After a labeled drawing of the pelvic anatomy, a close-up of the cervix locates the beginning of patient's cancer.

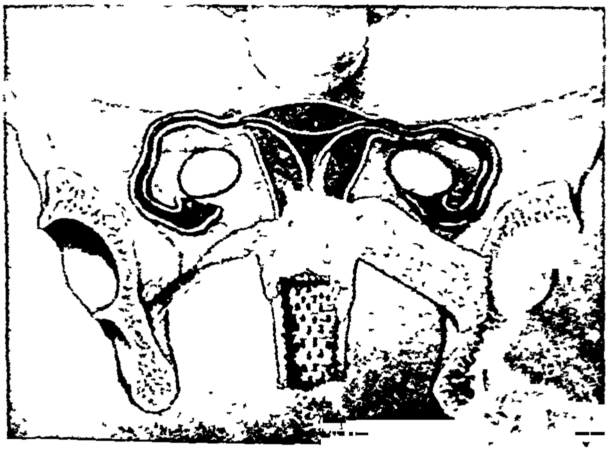

Fig. 4.—Animated sequence shows spread of cancer into endocervix, accompanied by increased bleeding. It continues to show classic pattern of extension into corpus uteri and para[illegible] Death followed shortly.

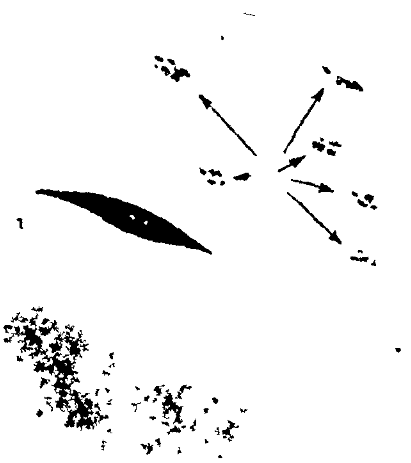

Fig. 5.—Normal process of cell exfoliation is explained. If cancer is present, among those cells will be found malignant cells.

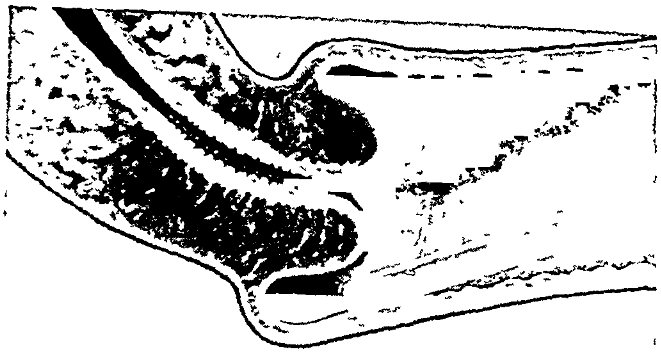

Fig. 6.—On sagittal view is illustrated the technique for removing a sample from the vaginal pool, using suction pipet. This procedure is painless to patient.

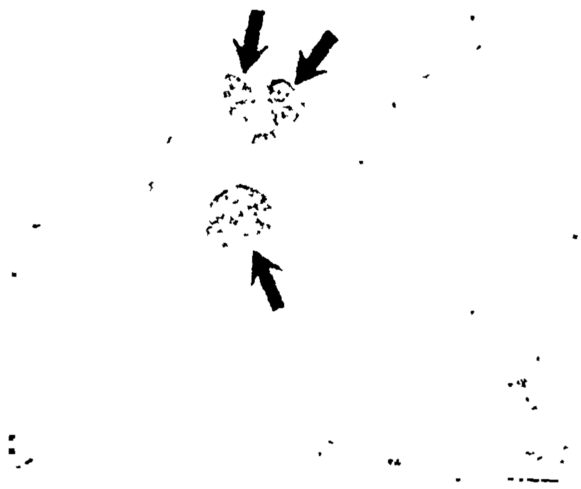

Fig. 7.—By noting cells' structural abnormalities in cervical smear, pathologist can suspect presence of cancer months, or even years, before it produces symptoms.

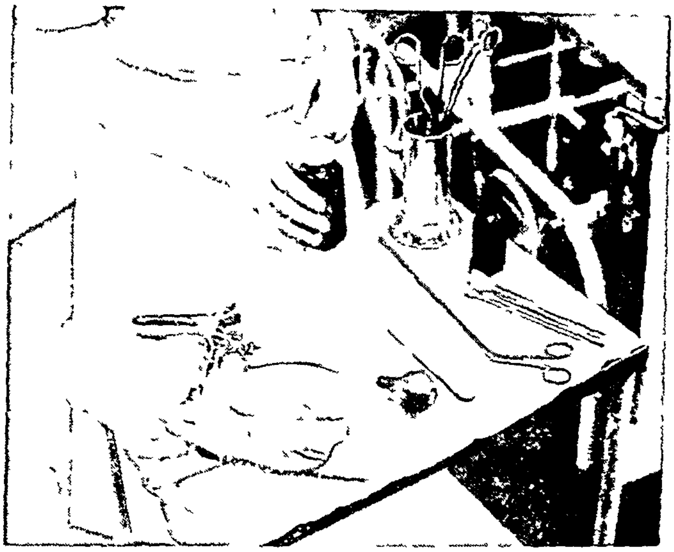

Fig. 8.—During yearly physical checkup of second patient, a cell specimen is taken for interpretation by the pathologist. Instrumentarium is shown and explained.

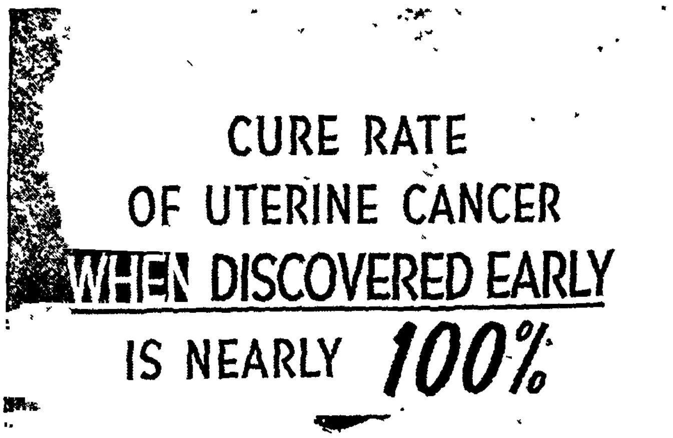
Fig. 9.—Laboratory report indicated presence of abnormal cells. Small tissue specimens removed from cervix confirmed positive diagnosis of cancer. Treatment followed, after which patient showed no further evidence of disease.



CURE RATE
OF UTERINE CANCER
WHEN DISCOVERED EARLY
IS NEARLY 100%

Fig. 10—Goal of physicians is to realize the full potential of curability of uterine cancer, which can be accomplished only with the help of all women.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Treatment of Active Chronic Infectious Hepatitis with ACTH (Corticotrophin) and Cortisone. P. M. Last. M. J. Australia 1:672-676 (May 18) 1957 [Sydney].

The term "active chronic infectious hepatitis" covers a group of patients with fairly well-defined clinical features, a highly characteristic pattern of biochemical findings, and a histological picture of the liver indicating active chronic inflammatory changes. It has been shown that corticotropin and cortisone are unsuccessful when used in the management of hepatic failure in advanced portal cirrhosis. This report is concerned with the effect of these drugs in the active chronic stage of the disease in 9 patients, an earlier report from this unit having presented observations on 34 patients with active chronic infectious hepatitis, of whom 18 died. The 9 patients included 5 men and 4 women. A detailed history was taken in all cases, including the assessment of diet, a search for contact with infectious hepatitis, a history of injections and transfusions, and possible exposure to hepatotoxic agents. Complete physical examination was repeated at intervals, and the patients were weighed regularly. At regular intervals the following biochemical estimations were performed: serum bilirubin content. cephalin flocculation, alkaline phosphatase content (in King-Armstrong units), and serum protein fractionation. The total serum lipids and the blood cholesterol content were determined.

Complete blood examination was performed in all patients on admission to hospital and repeated from time to time. Corticotropin and cortisone therapy were continued for periods ranging from 1 month to 3 years. One patient appears to have completely recovered, 2 have shown moderate improvement, and 3 have shown little or no benefit. Three patients died, but 2 of them improved subjectively while having hormone therapy. With the exception of 1 patient with severe cirrhosis, all patients showed prompt symptomatic improvement. which was not always sustained. No patient appears to have been made worse by hormone therapy. Histological material was obtained in 7 patients before the institution of hormone therapy. in 8 patients subsequently by serial liver biopsy. and at autopsy in the 3 fatal cases. In one patient liver biopsy indicated transient increase in activity, but in the rest no significant histological change could be attributed to hormone therapy. Sudden withdrawal of cortisone may precipitate acute relapse, even though the drug appears to have been producing very little effect. It is concluded that in the treatment of active chronic infective hepatitis, corticotropin and cortisone may produce varying subjective benefit and some improvement in the biochemical finding relating to liver function, but no significant histological change.

Problem of Carcinosarcoma: A Case of Gastric Neoplasm. J. C. Sanchez-Lucas and J. Villar-Bonet. Med. clín. 28:1-5 (Jan.) 1957 (In Spanish) [Barcelona, Spain].

There is a controversy among histopathologists as to whether a carcinosarcoma is a special type of tumor or only a carcinoma of atypical development, having large zones of anaplasia simulating sarcoma. The authors report histological studies of a gastric tumor which seem to prove that carcinosarcoma is not a special type of tumor. A woman 66 years old complained of gastric disorders of 2½ years' duration. The patient lost 12 kg. (26.5 lb.). A tumor could be felt on palpation. Roentgen examination of the stomach showed irregularities of the great curvature and a round shadow. A large tumor occupying the great curvature and several metastases were found at laparotomy. A total gastrectomy with cardioduodenal anastomosis was performed. The stomach contained a large tumor, occupying the great curvature, and a polyp. The histological study of the tumor revealed an adenocarcinoma in one portion of the tumor and a sarcoma in the other. Both portions were continuous through a band of disintegrated epithelial cords extending from the adenocarcinoma into the sarcoma portion. The polyp showed a transformation into an adenocarcinoma. The metastases were exclusively of the epithelial type. The findings in this case support the theory that carcinosarcoma is a carcinoma of atypical growth. Disintegration of the epithelial cords seems to be the causal factor of the transformation into sarcoma.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1948 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Hyperfunction and Hypofunction of Endocrine Glands and Diabetes Mellitus. P. G. Skillern and E. P. McCullagh. J. Indiana M. A. 50:701-709 (June) 1957 [Indianapolis].

Although the faulty carbohydrate metabolism that characterizes diabetes mellitus is traceable most frequently to dysfunction of the pancreas and resultant deficiency of insulin, other factors play important roles in carbohydrate metabolism, and their action sometimes causes diabetes or affects an existing diabetes. Diabetes mellitus may be produced by hyperfunctioning tumors of the pituitary, adrenal cortex, adrenal medulla, and thyroid and by hyperplasia of the adrenal cortex and thyroid. After surgical correction of the pathological condition, the diabetes may or may not be reversible. The authors cite patients with acromegaly in whom diabetes became reversed spontaneously, following treatment with cobalt teletherapy, or after treatment with estrogens. The diabetes due to Cushing's syndrome is usually corrected by surgical removal of the tumor or hyperplasia of the adrenal cortex.

One patient with Cushing's syndrome and pituitary tumor had a temporary remission of the diabetes after cobalt irradiation of the pituitary. The diabetes mellitus of 1 patient with pheochromocytoma, who was admitted in diabetic acidosis, disappeared after removal of the pheochromocytoma. The occurrence of diabetes mellitus in 2 patients with aldosteronism due to adrenal tumor suggests that a hormone may be secreted which has some corticoid action. Marked hyperglycemia during the administration of cortisone or permanent diabetes mellitus following the administration of exogenous cortisone is probably due to a preexisting latent or mild diabetes mellitus. A diabetic glucose-tolerance curve in a patient with hyperthyroidism may or may not be due to diabetes mellitus. An elevated fasting blood sugar level in the presence of hyperthyroidism is due to diabetes mellitus.

Generalized Intestinal Polyposis with Melanoplakia of Lips, Oral Mucosa and Fingers (Peutz-Jeghers Syndrome). V. R. Richterich and H. J. Kaufmann. Schweiz. med. Wchnschr. 87:552-558 (May 11) 1957 (In German) [Basel, Switzerland].

The concept of intestinal polyposis includes a number of disease entities that differ with regard to etiology and clinical aspects. Their common characteristic is the formation of multiple intestinal polyps of a precancerous nature. Realization of the possibility of cancerous degeneration of the polyps led to more intensive study of the forms that had been known for some time and to the discovery of new and little-known entities. The author lists 7 different forms of intestinal polyposis: 4 sporadically occurring nonfamilial, acquired forms and 3 hereditary familial forms. This report is concerned with one of the hereditary forms, the Peutz-Jeghers syndrome. When Peutz first described this entity in 1921, he called attention to the triad of heredity, pigmentation, and polyposis. More general attention was called to this form of intestinal polyposis by Jeghers and co-workers in 1949. The author found that so far 12 families have been reported in which more than 1 member was found to have the Peutz syndrome. Diagrams of the genealogical tree of 3 of these families show the appearance of the Peutz syndrome in successive generations.

The pigmentation appears in the form of melanoplakia in the perioral region, the oral mucosa, the fingers and toes. The spots on and around the lips are generally small and resemble freckles; those of the oral mucosa are usually larger. In some patients these spots are found also around the eyes and nose. On the hands and feet the spots show interdigital and sometimes volar or dorsal localization. In the differential diagnosis of the melanoplakial phakomatoses, endocrinopathies and nutritional disease must be ruled out. The most important symptom of the Peutz syndrome is polyposis of the small intestine particularly in the ileum and jejunum. In about half of the carefully examined patients polyps were found also in the stomach, and in about one third of the patients the colon and rectum were involved. In children this progressive disorder becomes manifest in recurrent episodes of invagination or gastrointestinal bleeding. In adults, signs of intestinal malignancy, such as bleeding and stricture, are frequently the first symptoms. The precancerous nature of the polyps is proved by the frequent occurrence of carcinoma in young adults and by the multifocal development of cancers. A dominant pleiotropic gene with high penetrance seems to be the cause of this disorder.

Aging of Arteries in Relation to Hypertension. J. Conway and K. S. Smith. Circulation 15:827-835 (June) 1957 [New York].

A new clinical method has been devised by the authors for the qualitative assessment of the elastic properties of the arterial reservoir. The method depends on changes in pulse pressure that occur after the inhalation of amyl nitrite as the blood pressure falls without change in heart rate. The test was applied to 16 normal young men and women between the ages of 17 and 32 years and to 52 patients with hypertension. Little change in pulse pressure accompanied the fall in diastolic pressure in the normal person after the inhalation of amyl nitrite (15% of the fall in diastolic pressure). In the hypertensive group, there were 15 patients with systolic or arteriosclerotic hypertension. In these patients the reduction in pulse pressure after the inhalation of amyl nitrite was 116% of the simultaneous fall in diastolic pressure. The remaining 37 patients with hypertension were grouped according to their responses to the elasticity test. In 20 patients the response was within the normal limits, and the average fall in pulse pressure was 28% of the fall in diastolic pressure—these patients were believed to have normally elastic arteries. In 17 patients the fall in pulse pressure was 96% of the fall in diastolic pressure, and it did not differ significantly from the response of the arteriosclerotic patients. They were therefore believed to have inelastic arteries.

Clinical differences between the patients with elastic and those with inelastic arteries strongly suggested that these patients had in fact different diseases. In one group the elevation of pressure appears to be the consequence of physiological aging of arteries and in the other group hypertension is imposed on a normal elastic arterial system. Those with elastic arteries were younger and had a higher initial diastolic blood pressure than those with inelastic arteries. The difference in age and in severity of hypertension suggests that the separation of hypertension into these functional types may be of considerable clinical value, and it offers some prospect of discerning the true nature of the disorder.

Anticoagulants in Acute Myocardial Infarction with a Comparative Analysis of Prognostic Factors. H. D. Chieffo. J. M. Soc. New Jersey 54:266-271 (June) 1957 [Trenton].

This study was originally undertaken to determine whether the anticlotting agents should be used routinely in acute infarction of the heart. All patients admitted to St. Francis Hospital in Jersey City, from January, 1950, to December, 1955, with acute myocardial infarction (confirmed by serial electrocardiograms or autopsy) who survived the initial 24 hours of hospitalization were included in this review. There were 140 patients. Anticoagulants were administered at the discretion of the attending physicians. They used these drugs most often in the poor-risk type of patient. A few practitioners, however, did use anticoagulants routinely. There were 63 patients treated with these drugs (group A) and 77 patients who did not receive them (group B). There were 9 deaths among the 63 patients treated with anticoagulants (14%) and 17 deaths among the 77 patients (22%) not treated with anticoagulants. In the group treated with anticoagulants there was a trend toward reduction of mortality in those with shock, congestive heart failure, previous myocardial infarction, hypertension, thromboembolism, diabetes mellitus, and pulmonary and renal disease. It is concluded that anticoagulants should be used in patients with these associated conditions.

The incidence of thromboembolic complications was equally low in patients who received anticoagulants as in those who did not. The difficulties involved in the diagnosis of this disorder may to some extent explain the low incidence noted. There were 2 deaths due to hemorrhage induced by anticoagulant drugs, and for this reason they must be used with extreme caution. They should not be used when there are contraindications such as peptic ulcer and other ulcerative lesions of the gastrointestinal tract, liver or renal disease, and hemorrhagic disorders. Anticoagulants should not be used routinely in patients with mild attacks of myocardial infarction who have no complications.

Experimental Studies of Mechanism of Action of Fat Embolism. E. Krönke. Arch. klin Chir. 285:308-340 (No. 3) 1957 (In German) [Berlin].

Artificial fat embolism was produced by intravenous injections in cats and dogs of a proprietary preparation of iodine in vegetable oil (iodipin), paraffin oil, and a suspension of Lycopodium spores. Graphic presentations of blood pressure values in the systemic and pulmonary circulations and of the respiratory changes occurring in the course of the animal experiments with iodipin, which remains locked up within the fine pulmonary vessels, revealed that death occurred only with complete obstruction of the pulmonary circulation. Reflex phenomena were produced not by oil embolism of the pulmonary vessels but by solid bodies, such as the Lycopodium spores.

The circulatory disturbances in pulmonary fat embolism are of a purely hydraulic nature and are the result of narrowing of the pulmonary vessels; they have no relation to the clinical aspect of shock. As a rule, pulmonary fat embolism may be considered harmless; it may gain importance only as an additional cause of death when it is associated with traumatic shock and other secondary injuries and disorders. In contrast, generalized fat embolism may exert a fatal effect when it affects vital areas of the central nervous system. Generalized fat embolism is produced predominantly by an overload placed on the pulmonary vessels by the fat emboli, i. e., by massive pulmonary embolization in the presence of normal heart action. In the animal experiments severe manifestations of shock and death were elicited by intra-arterial injections of smaller amounts of fat into the carotid artery. The author believes that traumatic fat embolism becomes significant mainly by the involvement of the central nervous system.

The conclusions drawn from these observations with respect to therapy of fat embolism in man are that in injured persons the frequently associated state of shock should be combated not with measures aimed at increasing the blood pressures but with agents which exert a damping effect on the autonomic nervous system, simultaneously inhibit the biological occurrence of lipase activity, and exert a mild depressive effect on the blood prestreated with anticoagulants was significantly lower than that in the group not so treated. The mortality in the treated group also compared favorably with other statistics on the prognosis in patients with coronary artery disease not treated with anticoagulants. Of the 275 patients treated with anticoagulants, the interval between diagnosis of angina pectoris and the institution of anticoagulant therapy was known in 266; this interval was less than 1 year in 134 and more than 1 year (with an average duration of symptoms of more than 4 years before the start of therapy) in 132. The mortality per year in these two groups was 2% and 8.1%, respectively, i. e., a significantly reduced mortality in the group treated within 1 year after the diagnosis, whereas statistics on the natural course of angina pectoris showed the highest mortality in the first year. The incidence of myocardial infarction during treatment with anticoagulants was significantly lower than in a corresponding period before treatment. The anginal distress, as measured by the effort tolerance, improved greatly in 38% of the patients and showed some improvement in an additional 12%. Improvement occurred gradually, reaching a maximum after 1 year of treatment and remaining fairly constant thereafter.

These results indicate that long-term anticoagulant therapy is effective in patients with angina pectoris. Among various factors which might possibly have influenced the course of the disease besides the anticoagulant itself, the placebo effect, psychosomatic effects initiated by the medical attention and reassurance of the patient, weight reduction, reduced tobacco consumption, and other changes in mode of life have been listed. It was not possible to draw definite conclusions concerning the relative importance of these factors, but weight reduction seems to improve the prognosis. The incidence of clinically significant hemorrhages caused by the anticoagulants alone was about 1 per 27 treatment-years, or about 1 per 20 treatment-years if patients with other causes of hemorrhage, such as peptic ulcer or ureteral stone, were also included.

The Clinical Use of Radioisotopes in the Differential Diagnosis of Anemia.

W. L. Hughes, P. C. Johnson, E. S. Berger and R. M. Bird. South M. J. 50:709-712 (June) 1957 [Birmingham, Ala.].

Cobalt-60-labeled vitamin B_{12} can be given orally and its absorption from the gastrointestinal tract measured. The basic defect in pernicious anemia is thought to be a permanent deficiency of gastric intrinsic factor so that adequate absorption of vitamin B_{12} from the gastrointestinal tract fails to occur. Since this defect is not influenced by parenterally administered vitamin B_{12}, the demonstration of faulty absorption of vitamin B_{12} from the gastrointestinal tract establishes the diagnosis of pernicious anemia despite previous treatment. The use of tagged cobalt as a diagnostic tool is illustrated by the cases of 3 men between the ages of 57 and 65 years. The first patient with progressive weakness and paresthesias in his lower legs, weight loss, and anemia, had been given bimonthly injections of vitamin B_{12} for 1 year, although a definite diagnosis had not been made. The clear-cut difference between the absorption of Co^{60}-labeled vitamin B_{12} with and without normal gastric juice made it possible to establish a diagnosis of pernicious anemia despite the long administration of the vitamin intramuscularly. The test thus solved a therapeutic problem, and the definite diagnosis was established without the need of withholding vitamin B_{12} and without the resultant risk of a neurological relapse. The second patient, with weakness and postprandial epigastric pain of 4 years' duration and paresthesias of the hands and feet of 4 months' duration, had sporadically been given oral preparations of iron and a variety of vitamins. The previous administration of hematinics, while failing to correct the hematological and neurological findings, had made it impossible to establish an accurate diagnosis by the examination of the blood or bone marrow. Co^{60}-labeled vitamin B_{12} excretion studies established the diagnosis of pernicious anemia, and on parenteral vitamin B_{12} therapy the patient obtained a complete hematological and neurological remission. In the third patient, with progressive weakness and attacks of sore mouth and tongue for 5 years, who had received irregularly intramuscular injections of both liver extract and vitamin B_{12}, the Co^{60}-labeled vitamin B_{12} excretion studies made it possible to establish that the patient had so-called nutritional macrocytic anemia but not pernicious anemia. It was interesting to note that subsequent studies in this patient revealed none of the more conventional laboratory evidence of impaired gastrointestinal motility and absorption, which are anticipated in a sprue-like syndrome. The patient made a dramatic recovery on administration of 10 mg. of folic acid daily.

Erythrocytes may be labeled with chromium-51 and be reinjected into the donor. One may then conveniently measure the rate of disappearance of the radioactivity from the circulation. From these data one can infer the rate of hemolysis. In a 13-year-old boy with attacks of anorexia, fever, and jaundice, increased erythrocytic fragility and hemolysis was demonstrated by estimation of Cr^{51}-labeled erythrocyte survival, and the diagnosis of congenital spherocytosis was made. The ability to demonstrate a hemolytic process despite the absence of anemia was of importance in the decision to perform splenectomy. The failure to demonstrate a shortened erythrocyte survival time by the Cr^{51} technique was interpreted as evidence against a hemolytic anemia and hence a contraindication to splenectomy in a 36-year-old man with exertional dyspnea and easy bruising of 1 year's duration. The subsequent failure to respond to splenectomy supported this view. In a third patient, with progressive weakness, dyspnea, hepatosplenomegaly, pancytopenia, and myelofibrosis of the bone marrow, Cr ^{51}-labeled red blood cell survival studies revealed increased hemolysis. Although the cause of the hemolysis was never determined, the apparent improvement after splenectomy would indicate that the pancytopenia was corrected by the operation. The evaluation of known anemias has often been an insoluble problem because of the widespread and casual use of proprietary compounds containing vitamin B_{12} and folic acid. Similarly, a search for a hemolytic element in anemia often has been unrewarding at a given moment. Tagged cobalt and chromium offer new diagnostic tools in such problems.

Acute Renal Failure: Experiences with Conservative and Hemodialysis Treatment in 32 Consecutive Cases. J. H. Thaysen, S. Gjørup and S.-A. Killmann. Dan. med. bull. 4:73-92 (May) 1957 (In English) [Copenhagen].

From May, 1955, to November, 1956, 32 patients with acute uremia were admitted to medical department A of the Rigshospital. Three patients died within 24 hours, 3 had a total anuria due to bilateral ureteral obstruction, and 26 had oliguria due to acute ischemic renal failure or other renal disease. Of the 26 patients, 18 were treated only conservatively, with 8 deaths. In 8 patients conservative treatment was supplemented by hemodialysis; 5 had acute ischemic renal failure, 1 patient had bilateral cortical necrosis, 1 had an actue exacerbation of chronic glomerulonephritis, and 1 had transitory oliguria due to chronic pyelonephritis. Three of the dialyzed patients died. The importance of the primary disease for the ultimate prognosis is stressed. Rational treatment prevents the development of hyperpotassemia, cerebral and pulmonary edema, and severe uremic intoxication, formerly frequent causes of death. Good conservative therapy is fundamental in the treatment of acute renal failure. Supplementary hemodialysis should probably be carried out on relatively liberal indications in order to prevent grave complications.

Leukaemia. R. B. Scott. Lancet 1:1162-1167 (June 8) 1957 [London].

The 2 common forms of chronic leukemia stand in sharp contrast: whereas the myeloid variety follows a stereotyped and constant pattern, the lymphatic may assume any of a dozen disguises. This paper is concerned with the lymphatic form of leukemia, which is marked by proliferation of lymphoid cells throughout the blood-forming organs; the cellular elements are usually mature; in the lymph nodes the proliferation is diffusely spread throughout the medulla; and the destruction and infiltration of the stroma, the histological signs of malignancy, are lacking. Most clinicians in Britain agree that it is the commonest type of leukemia seen today. It is likely that there has been a relatively greater increase in its incidence than in that of other types. There has always been a greater number of males affected than females, and in the present series of 227 patients, males made up 67.4% and females 32.6%. In 80% of the patients the first symptoms appeared between the ages of 40 and 70. The mean age at onset for the whole series was 58.2 years.

When the patient is first seen, the physical signs of the leukemia fall into 1 of 5 categories. The first is what may be called the "classic" form: in this, generalized enlargement of superficial lymph nodes is usually associated with palpable enlargement of the liver and spleen. In the present series the disease assumed this form in 73.2% of the patients. The second category is the splenomegalic type: these patients often complain of abdominal pain, and physical examination reveals massive splenomegaly of the order usually associated with chronic myeloid leukemia; there is commonly a lesser grade of hepatic enlargement; and no superficial lymph nodes are palpable. In this series 11.8% of the patients presented with this form. The third group includes patients who display enlargement of the lymph nodes of one superficial group or some other solitary tumor of lymphoid tissue. The onset was of this pattern in 7.3% of these patients. Specific skin infiltrations, although not rare, are seldom the presenting manifestation, only 2 of these patients (0.8%) coming into this group. In 6.9% no physical signs of disease were evident, and the characteristic changes in the blood were the only leukemic manifestations. Less common clinical features of chronic lymphatic leukemia fall into 2 groups; those depending on leukemic infiltrations in unusual sites, and those presumed to be the result of immunological disturbance.

As one watches patients with chronic lymphatic leukemia through their years of illness, it is possible to discern some pattern in the course of the disease. Usually there is a period of reasonable health, during which the lymph nodes and spleen increase slowly in size and the leukocyte count creeps upward, although the hemoglobin level and the platelet count are well maintained; then, with various degrees of abruptness, the advancing lymphoid infiltration determines bone marrow failure, the hemoglobin level falls, a hemorrhagic state appears, and, unless life is maintained by repeated transfusions, death follows from anemia and exhaustion. During the first phase, radiotherapy or chemotherapy will lower the leukocyte count and cause the lymph nodes to regress; in the second phase treatment is seldom of avail. At any time this course may be interrupted by the effects of infiltrations in such tissues as bone and skin, by infection, or by the appearance of one of the autoimmune syndromes. The length of the first phase varies from a few months to 8 or 10 years, and many of the older patients die with, rather than from, the disease. Rarely a patient appears to recover. In this series, a woman of 80 died of bronchopneumonia 10 years after the onset of chronic lymphatic leukemia; at the time of her death there were no enlarged lymph nodes nor splenomegaly, and the blood cell count was normal. In the present series the mean duration of the disease in 118 patients known to have died was 36.7 months. Survivals of 40 months in 30 untreated patients and 42 months in 50 irradiated patients again underline the fact that treatment has not improved the outlook in this disease.

The Complement Fixation Test in the Diagnosis of Amebiasis. C. G. Spicknall, J. Bosicevich, R. L. Black and others. Gastroenterology 32:1131-1142 (June) 1957 [Baltimore].

The records of 1,370 patients were reviewed on whom complement-fixation tests for amebiasis were performed. This test was found particularly valuable in the diagnosis of amebic liver involvement. The test in this complication of amebiasis was found negative in only 1 patient and doubtful-positive in 2 of 25 studied. The test was positive in intestinal amebiasis in 17.5% of the patients. Of 8 patients with amebic granuloma, only 1 had a positive test: 2 of these patients had Entamoeba histolytica in their stools and 2 had E. histolytica in the biopsy specimens from rectal lesions. The diagnosis of amebic colitis and its complications is difficult to establish. E. histolytica may not be found in amebic granuloma, in amebic hepatitis and abscess, and even in some cases of acute amebic colitis. The appearance of the lesions does not differentiate between amebic infection and other ulcerative diseases of the colon, even when there are ulcerations of the rectal mucosa. The appearance of lesions on roentgenologic study is no certain means of determining the causes of these lesions, whereas barium studies of the colon may suggest amebic disease.

Acute-Phase Protein in Rheumatic Fever. S. Rahman and P. Mozziconacci. Semaine hôp. Paris 34:2179-2186 (June 6) 1957 (In French) [Paris].

C-reactive protein is present at the beginning of an attack of rheumatic fever. The authors observed 52 patients with rheumatic fever and 13 patients with diseases of the same group in children aged 3 to 15. Acute-phase protein disappeared after 1 week of successful therapy with cortisone and prednisone. It reappeared in 15 patients during treatment with aspirin following the hormonal treatment. Six of the patients had a progressive type of rheumatic fever. The reappearance of C-reactive protein probably means that rheumatic fever is still active. The reactivation of rheumatic fever in 95% of cases occurred in the course of 4 weeks after the end of treatment. There was no C-reactive protein in patients with chorea. The presence of C-reactive protein does not establish that the rheumatic fever is active; its absence cannot reject its diagnosis. There is a threshold of the rheumatic fever progress beyond which C-reactive protein reappears. Clinicians found it present in rheumatic fever, glomerulonephritis, lipoid nephrosis, and in virus diseases such as measles, varicella, epidemic hepatitis, and primary infection with tuberculosis. The authors found it present also in leukemia and in typhoid. Stollerman presumes that disappearance of C-reactive protein is due to the hormone action on the inflammation, of which C-reactive protein is a manifestation. The disappearance of C-reactive protein means that rheumatic process is arrested but is not eliminated. The determination of the erythrocyte sedimentation rate, of the presence of C-reactive protein, of fibrinemia, and of the amount of mucoproteins are methods each of which determines the progress of the rheumatic fever. Any one method cannot be used to the exclusion of others. All of them help to observe the progress of the rheumatic process.

Effect of Prednisone in Pulmonary Silicosis. A. Slaviero and E. Gaffuri. Minerva med. 48:1522-1524 (April 28) 1957 (In Italian) [Turin, Italy].

Sixteen patients with silicosis who presented severe respiratory symptoms and who had not derived much benefit from the usual therapy were treated with prednisone for 31 days. The initial dose was of 30 to 40 mg. per day. A maintenance dose was administered as soon as the patients started to improve, and subsequently the dose was gradually diminished. Streptomycin was also administered to some patients in whom latent tuberculosis was suspected. Prednisone therapy had to be discontinued in 1 patient who presented a marked increase in blood pressure. The results were very good in 5 patients; their general condition improved and their respiratory symptoms regressed almost completely. Dyspnea at rest disappeared in 5 patients, and dyspnea on exertion diminished in 5 other patients. The drug had no effect on 3 patients with severe emphysema, 1 of them with chronic cor pulmonale. The drug had a beneficial effect on the cough of these 3 patients. Cough disappeared in 9 other patients and was checked markedly in the remaining 3. Roentgenologic examination did not show any changes.

Modern Treatment of Polycythemia Rubra Vera. U. Cardone and F. Galeazzi. Policlinico (sez. med.) 64:630-637 (April) 1957 (In Italian) [Rome].

Eight patients 32 to 65 years old with polycythemia vera were subjected to repeated removal of blood and to infusions of one-half or one-third of the amount of blood removed with fresh plasma from young donors. One patient had been treated previously with roentgen therapy and another with nitrogen mustard. Some patients already had marked symptoms of the disease and could do little or no work. The treatment was beneficial to all patients. The subjective condition of the patients started to improve after 2 or 3 transfusions. All symptoms had disappeared at the end of the treatment. The size of the spleen was reduced markedly and in some patients returned to normal. The patients could return to their work after the treatment. The hemoglobin level and blood pressure became normal in some patients. The effect of the treatment lasted for some months in some of the patients and for 1 to 2 years in the others. When the hematocrit and red blood cell values increased and the subjective symptoms returned the patients were subjected to a new course of treatment until their condition became normal. The treatment was repeated in one female patient once a year, and she was able to carry on with her occupation for the whole year. The treatment has not caused any complication.

Acute Barbiturate Intoxication. T. Koppanyi. J. Forensic Med. 4:65-71 (April-June) 1957 [Cape Town, South Africa].

Barbiturate coma is a form of anesthesia (light or deep) with varying degrees of areflexia, muscular relaxation, and other signs and symptoms characteristic of anesthesia. Small pupils indicate lighter and large pupils deep anesthesia. Mydriasis, therefore, is an unfavorable sign in barbiturate intoxication and is usually accompanied by marked decrease of the respiratory minute volume, by cyanosis, and very often by a fall in blood pressure and hypothermia. Hyperthermia, which is not infrequently seen in patients who have taken toxic amounts of barbiturates, is usually due to secondary infections, particularly pneumonia. In such cases, moist rales are discovered in the lower lung fields, which progress to bronchopneumonia with consolidation. Gross overdoses of barbiturates kill by direct depression of the respiratory center, and death may occur within an hour after oral ingestion. The majority of the patients do not take this absolute fatal dose, but only a fraction thereof, and may survive in an anesthetized state for 24 hours or more without any treatment. Then they die of respiratory and/or circulatory depression, pulmonary and cerebral edema, or pneumonia. Neither the symptoms nor the postmortem changes of organs and tissues differentiate barbiturate poisoning from other forms of coma or fatal central depression. The differential diagnosis therefore requires chemical identification of barbiturates in the blood and the urine during life, or in organs, particularly the liver and the brain at autopsy. The gastrointestinal contents should be saved for chemical analysis, because it is possible that small amounts of unabsorbed barbiturates are present, particularly when taken in tablet form.

Methods for the chemical identification of barbiturates in blood and tissue are described. The treatment of barbiturate poisoning may be symptomatic, analeptic, or directed toward the removal of barbiturates from the body. Symptomatic therapy includes maintenance of a patent airway and, when necessary, administration of oxygen through the airway, administration of parenteral fluids (2 to 3 liters every 24 hours), hypertonic solutions in patients with pulmonary edema, ascorbic acid to decrease permeability of blood vessels, antibiotics to prevent secondary infections (mainly pneumonia), frequent changing of the patient's position, and periodic slapping of the thorax to loosen bronchial secretions. The use of concentrated human albumin has been suggested for the prevention or treatment of cerebral edema. Picrotoxin and leptazol have been found to be most effective central analeptics in experimental and clinical acute barbiturate intoxication. Carefully supervised administration avoids convulsions and consequently excessively increased cerebral oxygen needs, as well as depression. Central analeptics act as physiological antagonists in barbiturate intoxication; they do not increase the metabolism or excretion of barbiturates. Massive intravenous infusions of isotonic dextrose or sodium chloride solutions in experimental animals (1) shortened the duration of narcosis from average anesthetic doses of barbital and phenobarbital from one-third to one-half that of controls, and (2) doubled the early elimination of these drugs in the urine. Animals receiving 2 or 3 fatal doses of barbital recovered completely under this treatment.

Taussig-Bing's Disease. A. Mispireta, G. Cornejo, A. Corvacho and others. Rev. peruana cardiol. 5:1-11 (Sept.-Dec.) 1956 (In Spanish) [Lima, Peru].

The case of Taussig-Bing's disease reported on by the authors is the first such to be reported from Peru. The diagnosis was made during the life of the patient and was verified by studies of his blood and by autopsy. The parents and family of the patient were normal. The patient was born apparently normal. The mother observed immediately after birth that the infant had palpitation, some dyspnea, and moderate cyanosis. When the patient was hospitalized at the age of 10 years, his mental age corresponded to that of a child 6 years old. He was in poor general condition, with marked cyanosis, acute dyspnea, and clubbed fingers. Phonocardiographic examination revealed accentuation and reduplication of the second pulmonary sound. Roentgen examination showed a complete transposition of the aorta, levoposition and enlargement of the pulmonary artery, and signs of hypertension in the pulmonary circulation. A diagnosis of Taussig-Bing's disease was made. A definite diagnosis was arrived at on determination of the oxygen content of the blood taken by cardiac catheterization. Oxygenation of the peripheral blood was poor. It was of about the same degree in the right ventricle and in the aorta but was increased in the pulmonary artery. The patient lived a few months after hospitalization and died of cardiac insufficiency. The anatomicopathological diagnosis was Taussig-Bing's disease with bivalve pulmonary artery.

Klebsiella Pneumonia Meningitis: Successful Treatment of Adult Case with Cortisone and Antibacterial Agents. R. L. Sterkel and W. A. Knight. Missouri Med. 54:519-524 (June) 1957 [St. Louis].

There are 2 features of meningitis due to Klebsiella pneumoniae: the relative rarity of the condition and the high mortality rate. Including the patient treated by the authors, only 133 instances of the disease have been reported. No age group is spared. The ratio of males to females is 65.6 to 34.4. Thompson and associates state that K. pneumoniae is the causative agent of meningitis in 0.16%. Before the advent of chemotherapy only 4 patients survived, and 2 of these were left with debilitating sequelae. Since the availability of the various sulfonamides and antibiotics, 33 recoveries are reported (50%); 3 of these patients had residual defects. The authors treated successfully a debilitated 79-year-old man with chronic alcoholism who had bacteremia and meningitis due to K. pneumoniae. The treatment consisted of sulfadiazine, penicillin, and streptomycin in conjunction with cortisone. The indications for the use of cortisone in this disease are proposed. There is a definite need for further evaluation, both clinical and experimental, of the role of adrenal steroids in infections.

Klebsiella Meningitis. A. P. Spivack, G. M. Eisenberg, W. Weiss and H. F. Flippin. Am. J. Med. 22:865-871 (June) 1957 [New York].

The authors report on 10 men and 1 woman between the ages of 35 and 80 years with meningitis due to Klebsiella. The focus of infection seemed to be the middle ear in 3, the lung in 2, and the frontal sinus in 1. In the remaining 5 patients there was evidence of recent trauma to the head in 4 and to the lower urinary tract in 1. Klebsiella could be demonstrated on direct smear of the spinal fluid in 6, and in 1 patient typing was done at the time of the smear on the fresh spinal fluid. The organisms cultured from the spinal fluid were typed in 7 patients; 6 were types 1 or 2 and 1 was type 8. One patient recovered and 10 died. Among the 10 patients who died, the hospital course varied from 1 to 6 days. Four patients received no antimicrobic therapy, 4 were treated with sulfonamides alone, 1 received penicillin and streptomycin, and 1 received the latter 2 drugs in addition to tetracycline and polymyxin. The only patient who recovered was treated with streptomycin, sulfadiazine, and penicillin. This patient was infected with type 8 Klebsiella, and there was a possible causative relationship to trauma of the lower urinary tract.

The 11 cases added to 140 collected from the literature make a total of 151 cases of meningitis caused by Klebsiella. The disease is often fulminating. Most cases have occurred in adults. Meningitis is usually secondary to Klebsiella infection of the respiratory tract, is most commonly due to types 1 and 2, and sometimes follows trauma to the head. Diabetes and debilitating diseases seem to be predisposing factors. Metastatic abscesses are frequent. The available information to date suggests that the drugs of choice are the sulfonamides. The status of the broad-spectrum agents, although promising, is equivocal because of the relatively few cases in which they have been used. In view of the serious nature of this form of meningitis it is recommended that both sulfonamides and broad-spectrum antibiotics be administered at once when a gram-negative encapsulated bacillus is found in the spinal fluid.

Aspiration Biopsy of the Parietal Pleura: Results in 45 Cases. R. F. Donohoe, S. Katz and M. J. Matthews. Am. J. Med. 22:883-893 (June) 1957 [New York].

Aspiration of the parietal pleura was performed in 29 men and 16 women between the ages of 15 and 83 years with pleural effusion in an attempt to establish the causation of this effusion. Adequate diagnostic tissue specimens were obtained in 33 patients (73%) and inadequate tissue specimens in 12 (27%). The histological diagnoses in the 33 patients were granulomatous pleuritis in 14, nonspecific pleuritis in 13, malignancy in 4, eosinophilic pleuritis in 1, and normal pleura in 1. Of 23 patients suspected clinically of having tuberculous pleuritis, this suspicion was confirmed by aspiration biopsy in 12. Of 11 patients with a clinical diagnosis of malignant pleural effusion, pleural biopsy specimens yielded evidence of malignancy in 4. Of 11 patients with effusion of undetermined causation, aspiration biopsy yielded adequate tissue specimens in 6 (54%); 2 specimens were consistent with a granulomatous pleuritis, 1 showed eosinophilic pleuritis, and 3 showed nonspecific pleuritis. There were no significant complications associated with aspiration biopsy of pleura.

Aspiration biopsy, a safe, easy, and accurate diagnostic method, thus was of considerable value in patients suspected clinically of having tuberculosis and was less often so in clinically indeterminate cases. The procedure was least useful in patients with malignancy, in whom pleural involvement may be spotty. The histological diagnosis of nonspecific pleuritis does not eliminate the possibility of either tuberculosis or malignancy as the causative disorder. In patients in whom this diagnosis is made after aspiration biopsy, an open biopsy should be performed if not contraindicated. The prime indication for aspiration pleural biopsy is so-called idiopathic pleurisy with effusion. The method, however, should be used as part of the basic evaluation of any effusion requiring diagnostic aspiration. The only contraindication would be a bleeding diathesis.

Renal Lesions of Scleroderma. G. Carpent. Acta clin. belg. 12:181-189 (March-April) 1957 (In French) [Brussels].

Scleroderma is no longer considered exclusively a dermatosis. Kidneys can also become involved, and changes in renal function do occur. Most patients with scleroderma show no symptoms of kidney involvement. The renal lesions become worse with the advancing age of the patient and give no clear indication of the extent of impairment of renal function. Autopsy of patients with scleroderma reveals that lesions identical with those accompanying clear renal insufficiency frequently are found in patients with no signs of renal insufficiency. These lesions are edematous hyperplasia of the intima of the interlobular arteries and fibrinoid necrosis of preglomerular arterioles. They are the same as the lesions of malignant nephroangiosclerosis. The author observed 4 patients with renal scleroderma, 3 of whom presented a correlation between the symptoms of malignant hypertension and the findings at autopsy of malignant nephroangiosclerosis. The 4th patient did not have hypertension, although the renal lesions were similar or identical with those of malignant nephroangiosclerosis. The patient, a 55-year-old male, was treated one year for scleroderma. When he entered the hospital his arterial tension was normal (120/80 mm. Hg), the blood urea content 180 mg. per 100 cc., and there was no albuminurea nor pathological cellular elements. The arterial tension never exceeded 150/90 mm. Hg. There were no symptoms of uremia. He died of bronchopneumonia. Here was discordance between the clinical symptoms and the findings of pathological anatomy. The author quotes the observations of other clinicians on patients with renal lesions of malignant nephroangiosclerosis but with no clinical signs of hypertension. Such observations seem to oppose the currently dominant theory that malignant nephroangiosclerosis occurs as a result of hypertension.

Pulmonary Adenomatosis: Six Cases. P. Purriel, D. Tomalino and S. Piovano. Tórax 6:5-28 (March) 1957 (In Spanish) [Montevideo, Uruguay].

Pulmonary adenomatosis consists of the development of unilateral or bilateral large intrapulmonary nodules of epithelial alveolar cells which merge into a tumor and give rise to metastases. The asymptomatic form is rare. The disease is detected during routine roentgen examination of the chest. The symptomatic form starts, as a rule, with a transient attack of febrile respiratory infection followed by bouts of bronchitis and respiratory symptoms of progressive severity. Bronchorrhea appears only in typical bilateral forms of the disease, depending on the presence of metaplasia of the alveolar mucinous cells. Expectoration consists of a foamy, watery, transparent fluid in daily quantities of 300 to 3,300 cc. In the course of the disease the fluid becomes purulent and later hemorrhagic. This type of bronchorrhea is pathognomonic. Blood spitting is rare. Except for a marked loss of weight, the general health of the patients remains fair for a considerable time. There are no diagnostic tests of specific value. Bronchoscopy is usually negative. Diagnosis is made on the basis of the following factors: (1) chronicity of respiratory symptoms and (2) the presence of a single unilateral or multiple bilateral nodules in the roentgenogram or of gray hepatization in the zone of the lung occupied by the tumor. A definite diagnosis is made on the finding of tumor cells in histological preparations of the sputum and on the results of pulmonary biopsy taken during a thoracotomy. The treatment consists of early lobectomy. This is contraindicated in the presence of symptoms of metastases, bronchopulmonary complications, and aggravations of the respiratory disorders. The duration of the condition varies between 1 year and more than 4 years.

The authors report 6 cases. The patients complained of marked loss of weight. Three patients were men between the ages of 40 and 62. The disease was bilateral and typical. The patients reported late when severe involvement of both lungs and symptoms of metastases contraindicated an operation. The patients died of asphyxia. Autopsy showed a large number of metastases in several viscera and metaplasia of the muciparous alveolar cells. The other 3 patients were women. Their disease was unilateral and asymptomatic, except in a patient who had hemoptysis. A diagnosis was made by lobectomy during a thoracotomy. Metastases occurred in all patients and were the cause of death.

The Significance of Bronchiectasis Associated with Pulmonary Tuberculosis. J. K. Curtis. Am. J. Med. 22:894-903 (June) 1957 [New York].

The author reports on 1 8-year-old boy and 7 men between the ages of 26 and 35 years with bronchiectasis associated with tuberculosis. The cases of the first 3 patients illustrate the 3 principal factors which appear to favor the development of bronchiectasis in tuberculous patients. In the boy, enlarged tuberculous hilar nodes compressed a bronchus; partial obstruction with cough, pooling of secretions, and tubercle formation in the more distal portion of the bronchial tree comprised the elements which lead to bronchiectasis. In a 27-year-old man, severe infiltration of the lung with tuberculous disease associated with a cavitary component presented the second and most common cause of tuberculous bronchiectasis. In a 29-year-old man, tuberculous endobronchitis led to destructive changes in the bronchial walls, resulting in bronchiectasis. The clinical features of tuberculous bronchiectasis are persistent cough and purulent sputum, often tending to subside as the result of antimicrobic therapy. The case of the 4th patient, a 35-year-old man, showed that hemoptysis may be a troublesome occurrence, that protracted bronchitis after an upper respiratory infection is a common sequence, and that at this time the sputum is most apt to be positive for tubercle bacilli. Significant pathological features of tuberculous bronchiectasis were observed in the right upper and middle lobes, which were resected in the 5th patient, a 28-year-old man. Tubercles often lie close to the epithelial surface; this is a dangerous situation when the overlying membrane is ulcerated and ragged. Many bronchiectatic lesions may communicate with cavities or liquefying nodular disease, hence providing a ready source for long-continued positive secretions. The bronchial walls may be greatly thickened by fibrous tissue which hinders the penetration of antimicrobic drugs. Nests of tubercle bacilli lodged in these sheltered areas lie dormant and can survive long periods; when liberated these organisms may cause further disease. The cases of the 3 remaining patients illustrate the importance of bronchiectasis in collapse therapy and surgical resection in patients with pulmonary tuberculosis. Tuberculous bronchiectasis caused failures in pneumothorax treatment and primary thoracoplasties. Careful appraisal of the involved lobe by planigrams and bronchograms is indicated before segmental resection in order to avoid complications associated with the type of tuberculous bronchiectasis which approaches dangerously near the intersegmental plane of dissection. Five patients are reported in whom new cavitary disease with communicating dilated bronchi developed in the segmental plane of a previous segmental resection. Bacteriological relapse was associated in 4, and resection was performed because of hemorrhage in 1.

Thoracic and Pulmonary Lesions Biopsied Under Thoracoscopic Vision. F. Heine. Beitr. Klin. Tuberk. 116:615-627 (No. 8) 1956-1957 (In German) [Berlin].

Diagnostic pulmonary punctures have been carried out with simple injection cannulas or with the puncture cannulas that are used for liver puncture. Many investigators regard aspiration biopsy of the lung as too dangerous and not sufficiently informative. The author describes a method that enables the examiner to obtain a biopsy specimen from the lung or from the inner wall of the thorax under thoracoscopic control; wide exposure of the thorax is unnecessary. It must be possible, however, to induce a (diagnostic) pneumothorax to an extent that instruments can be introduced with the aid of a trocar from 2 entrance punctures, as when thoracocautery is to be carried out. Illumination is furnished by a thoracoscope, and the biopsy specimen is obtained with a punch. The mouth of the punch is constructed in such a way that one jaw cuts over the other. This cutting action is important for the elastic pulmonary tissue. Furthermore the larger jaw of the punch has a cross bar so that the biopsy specimen will not slip out. The punch turns on its shaft so that the surface of the tissue to be biopsied can be approached in an optimal position. A diathermy sphere on a long shaft is available in order to arrest a possible hemorrhage. After the specimen has been obtained, 2 Monaldi catheters are introduced to remove the pneumothorax with the aid of a pump providing negative pressure.

The author presents 13 patients in whom the method was employed, and in 12 of them a diagnosis was established with the aid of the biopsy specimen. Serious complication, such as air embolism or infection of the pleural cavity, did not occur. When bleeding occurred it could be controlled with the aid of the diathermy sphere. In 10 of the 13 patients the lung had become completely reinflated on the second day after the intervention. The described method of pulmonary biopsy is superior to blind puncture because it is carried out under visual control at the site deemed optimal for diagnostic study; the biopsy specimen is of adequate size; and it is taken from the surface of the lung, so that the effect can be watched.

SURGERY

Arterial Embolectomy and Mitral Commissurotomy. P. Chalnot, R. Benichoux, C. Pernot and J. Dege. Presse méd. 65:1115-1118 (June 15) 1957 (In French) [Paris].

Arterial emboli in the limbs usually come from a thrombus formed in the left atrium after it has become enlarged as a result of mitral stenosis. The combination of arterial embolism and mitral commissurotomy has therefore become familiar to physicians. Patient with arterial embolism in the limbs may be treated by three methods: (1) the surgical removal of an embolus occurring some hours after mitral commissurotomy, which often has to be carried out as an emergency procedure; (2) mitral commissurotomy, with its necessary corollary, atrial thrombectomy, which may be deliberately decided on in a patient who has lately had an arterial embolectomy but which is not yet accepted as a standard procedure; and (3) embolectomy, if not amputation, which last may be the only possible treatment and which is still unfortunately the one most frequently used. These methods have been used by the authors in treating 49 cases of arterial embolism in the limbs (including the aortic arch) in 42 patients, 35 of whom also had mitral stenosis, either alone or in association with aortic involvement. The results obtained in these 35 patients provide a basis for comparative evaluation of the first 2 procedures as applied to patients with mitral stenosis.

The second procedure, that is, commissurotomy after an arterial embolectomy, was used in 23 patients, 21 (91%) of whom have survived. Two of the patients have a follow-up of only 6 months and 10 months, respectively, but in all the rest the follow-up ranges from 1 to 3 years. These results contrast sharply with those obtained in 8 patients who, for various reasons, were treated by embolectomy alone, without a subsequent commissurotomy, 6 of whom died within from 2 days to 6 months, 3 from cerebral embolism and 3 from cardiac insufficiency and myocardial failure. One of the remaining 2 has been lost to follow-up and the other, 6 months after operation, presented signs of uncontrollable myocardial insufficiency. Mitral commissurotomy after embolectomy therefore appears to be the treatment of choice in patients with mitral stenosis associated with arterial emboli in the limbs.

Mitral commissurotomy, however, still presents many difficulties when the left atrium is thrombosed. Attempts have been made to overcome these difficulties and to prevent massive peroperative embolism by gentle manipulation and complete curettage of the atrium, but these measures are not entirely satisfactory. The authors have devised a small instrument resembling an umbrella, called the parathrombus, which is designed to prevent the passage of thrombi through the mitral orifice. Blood passes freely through the fabric of the instrument but the thrombi are trapped by it as they are dislodged and can be removed all at once when the instrument is closed and withdrawn from the atrium.

The authors believe that the large amounts of blood often lost during commissurotomy complicated by atrial thrombosis should be replaced so that the blood volume and arterial pressure are restored. This will force small embolic particles toward the most peripheral arteries, where a collateral circulation can easily become established and where obliteration is better tolerated.

Results of Surgery in the Treatment of Pulmonary Tuberculosis. S. J. Viikari, V. Autio and P. Antila. Ann. chir. et gynaec. Fenniae 46:205-216 (No. 2) 1957 (In English) [Helsinki].

Of 329 patients with pulmonary tuberculosis operated on with the aid of endotracheal anesthesia, extrapleural pneumothorax was performed in 133, thoracoplasty in 117, and pulmonary resection in 79. All the patients had been treated with streptomycin, aminosalicylic acid, and isoniazid for 3 to 6 months before the operation, and the antituberculous drug therapy was continued for from 3 to 6 months postoperatively. The primary mortality in the extrapleural pneumothorax groups was 0.8%, and favorable results were obtained in 93.7% of the patients. The longest follow-up period in this group was 3 years, and only 5 patients were followed up for periods from 3 to 6 months. The extrapleural pneumothorax was terminated about 18 months after its induction, and the lungs had expanded without difficulty. The primary mortality in the thoracoplasty group was 5.1%. Favorable results were obtained in 82% of the patients. The longest follow-up period was 4 years, and 7 patients were followed up for from 3 to 6 months. Of the 79 patients in the resection group, 18 had a pneumonectomy, 6 a lobectomy combined with segmental resection, 27 a lobectomy, and 28 a segmental resection. Two of the 18 patients who had pneumonectomy died, a primary mortality of 2.5%. Bronchial fistula occurred in 2 patients, and empyema appeared in the resected area in 1 patient. The results were favorable in 74 patients (93.7%), but 24 of these had been followed up for only 3 to 6 months.

Of 316 patients in whom follow-up examinations were carried out, 287 (90.8%) obtained favorable results from surgical procedures, 12 (3.8%) had died, and 17 (5.4%) still had Mycobacterium tuberculosis in their sputums. In the assessment of the relative merits and disadvantages of the various surgical procedures, the evaluation of the postoperative function of the lungs is of primary importance besides the recovery rate. Only follow-up examinations of large series of patients can give a reliable answer concerning this problem. In the authors' experience the decrease in pulmonary function resulting from extrapleural pneumothorax and particularly that resulting from segmental resection varies greatly in the individual patient and can be predicted only with difficulty in borderline cases. The decrease in function after a 5-rib thoracoplasty is constantly slight and can be predicted more easily even in borderline cases.

On the Surgical Treatment of Chylothorax Due to Traumatic Lesions of the Thoracic Duct in the Thorax: Experimental Research. L. Giordano. Minerva med. 48:1515-1519 (April 28) 1957 (In Italian) [Turin, Italy].

Experimental chylothorax was produced in 6 large dogs, 4 of which were subsequently subjected to surgical treatment for the correction of this condition. Symptoms of chylothorax appeared in the 4 dogs 2 weeks after they had been operated on. The other 2 dogs were killed 2 months after the operation. Some clear yellow liquid was found in the pleural cavity of these 2 dogs at autopsy; the lungs and the heart were normal, the lymph nodes were not enlarged, and there was no ascites. The animals with chylothorax were operated on atfer 15 to 20 days while they were still in condition to survive the operation. The animals were anesthetized and intubated. Two to 3 cc. of a blue-colored vital lymphatic substance was injected in the interdigital space of the left hind leg. An incision was then made on or near the scar of the operation through which chylothorax had been created. A large quantity of the colored substance was found after opening of the pleura. The ends of the resected duct were easy to find, thanks to the blue color which they had assumed. A silk ligature was placed on either end of the resected duct, and the thorax was closed. All the animals recovered and were killed 1 to 3 months after the second operation. Lymph was not found at autopsy, the duct was occluded, and there was evidence that collateral lymphatic channels had developed.

Pancreatoduodenectomy for Carcinoma of the Pancreas in an Infant: Report of a Case. W. F. Becker. Ann. Surg. 145:864-870 (June) 1957 [Philadelphia].

A 15-month-old boy was admitted to a New Orleans hospital in January, 1956, because of massive hematemesis and melena of 6 hours' duration. He was considered normal during the first six months of life; then he began to eat poorly, failed to gain weight, refused to play, and experienced abdominal pain. A hard, nontender, movable mass produced a visible prominence of the upper anterior abdominal wall. Contrast studies of the stomach and duodenum suggested that an enlarged duodenal bulb and a widened duodenal loop were stretched around a mass which lay within the duodenal loop. The roentgenographic diagnosis was "mass arising in the head of the pancreas." Exploratory laparotomy was advised but refused, and the patient was discharged from the hospital. Ten days later he was admitted to another hospital because he had again passed multiple bright red stools. While the child was being prepared for an elective operation, massive hematemesis and melena recurred, and emergency laparotomy was required. The preoperative diagnosis, based largely upon roentgenographic findings, was tumor of the head of the pancreas with extension into the duodenum and massive hemorrhage. At operation the proximal two-thirds of the pancreas was found to be replaced by a hard, fairly well circumscribed, 7-cm. mass. The spleen was twice the normal size, and there were many dilated tortuous veins at its hilum.

Resection of the distal half of the stomach, proximal three-fourths of the pancreas, gallbladder, common bile duct, duodenum, and proximal jejunum was performed. Reestablishment of the gastrointestinal and the biliary-intestinal continuity was effected by a hepaticojejunostomy and a gastrojejunostomy. At the most recent examination, 10 months after the operation, when the boy was 25 months, he appeared normal. The author cites the 6 authenticated cases of primary carcinoma of the pancreas in persons under 13 years of age. This is believed to be the first report of a pancreatoduodenectomy in an infant.

Duodenal Ulcer Treated by Gastro-enterostomy with Vagotomy. F. D. Hindmarsh. Lancet 1:1113-1115 (June 1) 1957 [London].

The author reviews observations on 197 patients with duodenal ulcer in whom he performed vagotomy and posterior gastrojejunostomy according to a standardized technique. The patients selected for this operation were those in whom chronic ulcer or scarring was demonstrated roentgenologically and confirmed by laparotomy. Acute hemorrhage, in which partial gastrectomy may be life-saving, is a contraindication to gastroenterostomy with vagotomy. To ascertain the results of the surgical treatment, each patient was interviewed at the end of the first year and was later sent circular letters. Of the 197 patients operated on, 1 died after the operation and 2 subsequently from cerebral hemorrhage, and 1 was not traced, leaving 193, all of whom were reviewed in the last 6 months. The author found that the results to date of the standardized procedure of vagotomy combined with a large stoma, drainage, and posterior gastrojejunostomy were encouraging, since they were satisfactory in 189 and unsatisfactory in only 4 of the patients. This review supports the opinion of Oberhelman and Dragstedt in 1955 that, provided vagotomy is complete and drainage adequate, the results will compare favorably with any other operation so far devised to treat duodenal ulcer.

Pancreatitis, a Diagnostic Clue to Hyperparathyroidism. O. Cope, P. J. Culver, C. G. Mixter Jr. and G. L. Nardi. Ann. Surg. 145:857-863 (June) 1957 [Philadelphia].

The diagnosis of hyperparathyroidism generally depends upon the presence of a complication of the primary metabolic disorder. In only a rare instance has the disease been identified in the absence of the classic bone disease, urinary tract calcification, or peptic ulceration. The symptoms due to the hypercalcemia itself, such as fatigue, lassitude, and dyspepsia, are so uncharacteristic and so common in the population that dependence upon them to call the diagnosis to the attention of the clinician has proved unrewarding. The authors present the histories of 2 patients with hyperparathyroidism treated at the Massachussetts General Hospital who also had pancreatitis. Acute pancreatitis became evident in the first patient during a phase of known hyperparathyroidism. In the second, who was under treatment for recurrent pancreatitis, the diagnosis was established fortuitously. These experiences, one the converse of the other, suggested that pancreatitis is another complication of hyperparathyroidism. If this is true, all patients with pancreatitis should be screened for hyperparathyroidism. Patients believed to have hyperparathyroidism may develop pancreatitis. The striking features in these 2 patients prompted a review of the literature. It was found that the association of hyperparathyroidism and pancreatitis, either with or without pancreatic calculi, had been recorded in isolated case reports.

Consideration of a causal relationship between pancreatitis and hyperparathyroidism hinges on which disease plays the primary role. It appears likely that the overactivity of the parathyroids initiates the pancreatitis, although the reverse is possible. The authors visualize the following sequence of events: (1) the development of hyperparathyroidism, (2) the formation of pancreatic calculi, either superimposed on tissue trauma or as a primary precipitation of calcium, and (3) ductal obstruction and pancreatitis. The prompt subsidence of the pancreatitis following parathyroid adenomectomy in 1 of the 2 patients may be explained by the relief of ductal obstruction upon resorption of the calculi following the return of a normal serum calcium level.

Management of Intussusception in Infants and Children. J. F. Langlet and D. P. Chance. A. M. A. Arch. Surg. 75:35-40 (July) 1957 [Chicago].

Intussusception is seen most frequently in the first 2 years of life and constitutes one of the most common abdominal emergencies. Intussusception may be reduced by air insufflation or enemas, and at the time of operation by manual taxis. Patients with intussusceptions which are irreducible by the above means or are gangrenous may be treated by a variety of surgical means: (1) resection with immediate anastomosis; (2) resection with formation of a double-barreled enterostomy and subsequent closure; (3) suture of the serosa of the invaginated barrel of the intussuscipiens, followed by resection of the gangrenous intussusception through an incision in the ensheathing intestine; (4) lateral anastomosis about the lesion; (5) ileostomy with secondary resection; and (6) various combinations of the above. Of the 19 children admitted with acute intussusception, the etiological factor was found to be a Meckel's diverticulum in 2 and an ileal polyp in 1. In the remainder the intussusception was of the idiopathic variety. The age range of the 14 boys and 5 girls was from 1 month to 2½ years. The parents gave a history of a well baby who suddenly began to have acute, colicky abdominal pain, which recurred in association with vomiting and bloody stools. The patients appeared some time after onset to be pale, listless, dehydrated, and acutely ill, with a rapid pulse. The abdomen was frequently distended, palpation revealing a sausage-like mass. Barium enemas, attempted in 16 cases, were successful in the reduction of the intussusception in 6 of the 19 cases in this series. No reduction or incomplete reduction was effected in 9 cases, the barium enema studies being within normal limits in 1 patient with an ileoileal intussusception. Of the 13 patients requiring surgical management, spontaneous reduction was found to have taken place in 2 and reduction by manual taxis was completed in 7; in 4 cases the intussusception was irreducible or gangrenous, requiring resection. A better understanding of the management of body fluids and electrolytes, recently developed antibiotics, and improved pediatric and anesthetic care have greatly reduced the mortality rate in the past decade. Packard reported a 50% mortality rate in 4 cases in the period 1934 to 1944 and no mortality in the 8 cases treated in the period 1944 to 1954. Dennis reports 8 consecutive successful resections and Thatcher reports a 6% mortality in 15 cases requiring resection from 1947 to 1953 in contrast to a 55% mortality in 20 cases prior to that time.

Spine Fusion in Young Children: A Long-Term End-Result-Study with Particular Reference to Growth Effects. H. Hallock, K. C. Francis and J. B. Jones. J. Bone & Joint Surg. 39A:481-491 (June) 1957 [Boston].

A clinical and roentgenographic study was made of the effects of spine fusion on the growth of the fused vertebrae in 15 patients, 5 male and 10 female, who had been subjected in early childhood to a Hibbs type of spinal fusion for tuberculosis and who were followed into adolescence and adult life for from 12 to 31 years. Fusion was successful in all patients, and the lesions of the spine healed. Since in all of these patients at least 2 normal vertebrae had been included in the fusion above and below the diseased area, a unique opportunity was offered to study the effects of arthrodesis on growth in fused normal vertebrae as well as in diseased vertebrae.

The growth changes observed were narrowing of the intervertebral disk spaces in the fusion area with occasional partial obliteration, a trapezoid development of the end vertebrae, and underdevelopment of the fused vertebral bodies in both the sagittal and frontal planes. Whenever possible measurements were made directly on lateral roentgenograms of the entire fused area, 2 normal-appearing vertebrae included in the fusion above and below the diseased area, and 2 or 3 normal contiguous vertebrae above and below the fusion. The measurements made on early postoperative roentgenograms were compared with those on late roentgenograms showing final results. The end-results were compared with the original measurements in terms of percentage increase over 100, in order to eliminate the error of unknown early target-to-tube distance and an increase in the target-to-spine distance caused by growth in thickness of the patient. It was found that considerable variation of growth occurred even in persons of similar age at operation. On an average, the entire fusion area grew anteriorly 37% less and posteriorly 45%

digital space of the left hind leg. An incision was then made on or near the scar of the operation through which chylothorax had been created. A large quantity of the colored substance was found after opening of the pleura. The ends of the resected duct were easy to find, thanks to the blue color which they had assumed. A silk ligature was placed on either end of the resected duct, and the thorax was closed. All the animals recovered and were killed 1 to 3 months after the second operation. Lymph was not found at autopsy, the duct was occluded, and there was evidence that collateral lymphatic channels had developed.

Pancreatoduodenectomy for Carcinoma of the Pancreas in an Infant: Report of a Case. W. F. Becker. Ann. Surg. **145:**864-870 (June) 1957 [Philadelphia].

A 15-month-old boy was admitted to a New Orleans hospital in January, 1956, because of massive hematemesis and melena of 6 hours' duration. He was considered normal during the first six months of life; then he began to eat poorly, failed to gain weight, refused to play, and experienced abdominal pain. A hard, nontender, movable mass produced a visible prominence of the upper anterior abdominal wall. Contrast studies of the stomach and duodenum suggested that an enlarged duodenal bulb and a widened duodenal loop were stretched around a mass which lay within the duodenal loop. The roentgenographic diagnosis was "mass arising in the head of the pancreas." Exploratory laparotomy was advised but refused, and the patient was discharged from the hospital. Ten days later he was admitted to another hospital because he had again passed multiple bright red stools. While the child was being prepared for an elective operation, massive hematemesis and melena recurred, and emergency laparotomy was required. The preoperative diagnosis, based largely upon roentgenographic findings, was tumor of the head of the pancreas with extension into the duodenum and massive hemorrhage. At operation the proximal two-thirds of the pancreas was found to be replaced by a hard, fairly well circumscribed, 7-cm. mass. The spleen was twice the normal size, and there were many dilated tortuous veins at its hilum.

Resection of the distal half of the stomach, proximal three-fourths of the pancreas, gallbladder, common bile duct, duodenum, and proximal jejunum was performed. Reestablishment of the gastrointestinal and the biliary-intestinal continuity was effected by a hepaticojejunostomy and a gastrojejunostomy. At the most recent examination, 10 months after the operation, when the boy was 25 months, he appeared normal. The author cites the 6 authenticated cases of primary carcinoma of the pancreas in persons under 13 years of age. This is believed to be the first report of a pancreatoduodenectomy in an infant.

Duodenal Ulcer Treated by Gastro-enterostomy with Vagotomy. F. D. Hindmarsh. Lancet 1:1113-1115 (June 1) 1957 [London].

The author reviews observations on 197 patients with duodenal ulcer in whom he performed vagotomy and posterior gastrojejunostomy according to a standardized technique. The patients selected for this operation were those in whom chronic ulcer or scarring was demonstrated roentgenologically and confirmed by laparotomy. Acute hemorrhage, in which partial gastrectomy may be life-saving, is a contraindication to gastroenterostomy with vagotomy. To ascertain the results of the surgical treatment, each patient was interviewed at the end of the first year and was later sent circular letters. Of the 197 patients operated on, 1 died after the operation and 2 subsequently from cerebral hemorrhage, and 1 was not traced, leaving 193, all of whom were reviewed in the last 6 months. The author found that the results to date of the standardized procedure of vagotomy combined with a large stoma, drainage, and posterior gastrojejunostomy were encouraging, since they were satisfactory in 189 and unsatisfactory in only 4 of the patients. This review supports the opinion of Oberhelman and Dragstedt in 1955 that, provided vagotomy is complete and drainage adequate, the results will compare favorably with any other operation so far devised to treat duodenal ulcer.

Pancreatitis, a Diagnostic Clue to Hyperparathyroidism. O. Cope, P. J. Culver, C. G. Mixter Jr. and G. L. Nardi. Ann. Surg. **145:**857-863 (June) 1957 [Philadelphia].

The diagnosis of hyperparathyroidism generally depends upon the presence of a complication of the primary metabolic disorder. In only a rare instance has the disease been identified in the absence of the classic bone disease, urinary tract calcification, or peptic ulceration. The symptoms due to the hypercalcemia itself, such as fatigue, lassitude, and dyspepsia, are so uncharacteristic and so common in the population that dependence upon them to call the diagnosis to the attention of the clinician has proved unrewarding. The authors present the histories of 2 patients with hyperparathyroidism treated at the Massachussetts General Hospital who also had pancreatitis. Acute pancreatitis became evident in the first patient during a phase of known hyperparathyroidism. In the second, who was under treatment for recurrent pancreatitis, the diagnosis was established fortuitously. These experiences, one the converse of the other, suggested that pancreatitis is another complication of hyperparathyroidism. If this is true, all patients with pancreatitis should be screened for hyperparathyroidism. Patients believed to have hyperparathyroidism may develop pancreatitis. The striking features in these 2 patients prompted a tients), and occasionally weight loss (in 9 patients). The average duration of symptoms was well over 3 years. In some patients the symptoms existed for as long as 45, 20, 18, 17, 15, 12, and 10 years. All of these patients with long histories were apparently cured by resection. However, 2 patients with a 6-year and 7-year history, respectively, died of generalized metastases 2 and 4 years after surgery. Thus the usual prolonged course bears no relationship to curability. Bronchoscopic resection is not a reliable method of treatment. Cure requires transthoracic excision of the tumor and removal of lymph nodes. The extent of lung resected depends largely on the extent of irreversible changes in the pulmonary tissue. Early intervention will conserve lung and, in some patients, will permit local excision by bronchotomy. Treated surgically, bronchial adenoma has the best prognosis of any lung tumors with a malignant potential.

Malignancy of Solitary Adenomas. K. Keminger. Klin. Med. 12:233-240 (June) 1957 (In German) [Vienna].

Of 15,700 thyroidectomies performed at the surgical department of the Empress Elizabeth Hospital, in Vienna, between 1945 and 1955, 1,290 were done for solitary adenoma and 9,678 for multiple adenoma. Of the 1,290 solitary adenomas, 33 (2.55%) were malignant or suspected to be malignant, while of the 9,678 multiple adenomas 122 (1.26%) were malignant or suspected to be malignant. Solitary adenomas thus are twice as frequently malignant as multiple adenomas. Of the 33 malignant solitary adenomas, 7 occurred in patients between the ages of 20 and 30 years and 9 in patients between the ages of 40 and 50 years; patients in the younger age groups, therefore, have been predominantly affected, while an increase in the incidence of all the malignant goiters occurs only with advanced age (age of carcinoma). Of the 33 solitary adenomas, 9 were papillary adenocarcinomas, 5 malignant adenomas, 4 Langhans' goiters, 1 Hürthle-cell tumor, and 14 were suspected to be malignant. The large number of tumors suspected to be malignant shows how difficult the decision is whether or not the tumor is to be considered malignant. The number of borderline cases is particularly great in the thyroid in which the microscopic picture is highly polymorphous and the boundary between a marked tendency to proliferation and atypical, already malignant growth is indistinct. The development of solitary adenoma seems to have an origin which differs from that of multiple adenoma; while multiple adenoma probably represents a form of hyperplasia, the development of the solitary adenoma seems to correspond more to that of a tumor. The high incidence of malignant adenomas in patients with single nodules makes increased caution advisable but does not justify surgical treatment of every goiter in young patients in whom a nodule may be palpated, since solitary adenomas the presence of which is suspected from palpation findings are rarely solitary in reality.

Ligation of the Internal Mammary Arteries in the Treatment of Patients with Angina Pectoris. F. De Matteis, C. Barocelli and G. Barbano. Minerva med. 48:1920-1926 (May 30) 1957 (In Italian) [Turin, Italy].

Twelve patients, 45 to 65 years of age, with angina pectoris were subjected to ligation of the 2 internal mammary arteries in the second intercostal space. Six patients presented myocardiosclerosis with electrocardiographic signs of ischemic damage, a well-compensated general circulation, and anginal syndrome only on exertion. The remaining 6 patients presented a postinfarction anginal syndrome which they had developed at least 3 months after the infarction. Previous medical treatment had no beneficial effect in all 12 patients. The operation produced immediately satisfactory results in 8 of the 12 patients; stenocardial disturbances disappeared completely or in part. The results were very good in 4 patients and good in the other 4. Electrocardiographic improvement occurred in only 2 of the 8 patients. This improvement was already marked in one patient 2 hours after the operation; normal values were observed 48 hours after the operation. The same patient had a relapse 3 months after the operation; stenocardial episodes and mild ischemia were observed. Observations made one year after the operation showed that the subjective condition of the 8 patients had remained good. Some improvement was noticed in one of the 4 patients in whom the operation had had no immediate beneficial effect. One patient died 8 days after the operation because of bronchopulmonary involvement. Changes in the size of the heart were not observed.

Surgical Treatment by Pulmonary Exeresis in Tuberculous Children. C. Wapler, A. Libert and B. Voisin. Presse méd. 65:1143-1146 (June 19) 1957 (In French) [Paris].

Resection is suggested as a method complementary to the administration of antibiotics, in cases where antibiotics alone fail to accomplish a cure of tuberculous lesions. The authors performed pulmonary resection on 26 children, aged 8 to 16, of whom 16 were girls and 10 boys. The children came from poor homes. Their medical history was unknown, and they had received no antibiotics before admission to the hospital. The course of the disease was advanced at the time of the operation. The results of operation were satisfactory; 23 children made a good recovery and 2 relapsed, and antibiotic treatment was resumed for them. The indication for resection in a child is advanced stage and numerous lesions in puberty. Resection is more clearly indicated in children than in adults. Postoperative spread of lesions was observed in 2 patients. A systematic description of the lesions can be obtained by comparing the anatomic and the pathological features with the clinical and radiologic findings. Only such a description will determine the limits of indication for surgical therapy.

Gastric Glomus Tumor: Report of Case and Review of Literature. E. Shocket, H. C. Moeller, E. L. Cheatle and others. Gastroenterology 32:1145-1151 (June) 1957 [Baltimore].

A 66-year-old patient with myelofibrosis and compensatory hematopoiesis of the liver and, presumably, of the spleen, was found on roentgenogram to have a persistent defect in the antrum of the stomach. Laparotomy with local excision established the gastric lesion to be a glomus tumor. The patient was followed for 9 months after the operation. His vigor had returned, although he was still troubled by easy satiety. Roentgenograms of the stomach revealed some deformity of the antrum at the operative site, which was significantly smaller than it had been 5 months after the operation, and was compatible with postoperative scarring. This patient was the 8th with gastric glomus tumor reported on in the literature. The typical epithelioid appearance of these tumors allows them to be confused with carcinoids. The occurrence of glomus tumors in regions of the body where normally there are no glomera is explained. All but one of the patients with gastric glomus tumor were males; the patients were over 40 years of age. Gastrointestinal bleeding was present in half of the patients. A definite ulceration was demonstrated in the mucosa overlying the tumor. The tumor itself was usually somewhat encapsulated and found in the submucosa or muscularis. None of these tumors was considered malignant. Local excision would seem adequate treatment of a known glomus tumor.

Cardiac Monitor for Detection and Differentiation of Cardiac Standstill, Ventricular Fibrillation, or Peripheral Vascular Collapse During Surgery. R. Simpson, B. Abrams and A. S. Gordon. Surg. Gynec. & Obst. 105:110-113 (July) 1957 [Chicago].

A relatively low incidence of permanent survival after cardiac arrest (cardiac standstill or ventricular fibrillation) results from failure to recognize the condition immediately and resultant delay in starting effective therapy. Cardiac resuscitation is usually successful if there has been proper diagnosis and institution of adequate therapy within 4 minutes from time of onset. The most common cause of poor outcome is failure to detect the condition, as the bulk of the reported series are those of large general hospitals with staffs well indoctrinated in the immediate treatment of cardiac standstill, ventricular fibrillation, and peripheral vascular collapse. The practical cardiac monitor used here is a small, simple, portable, inexpensive, explosion-proof, transistorized, battery-powered unit which provides a continuous instantaneous visual pattern of the electrical activity of the heart. It has proved reliable and efficient in reflecting tachycardia, bradycardia, and extrasystoles and has accurately detected cases of cardiac standstill, ventricular fibrillation, and peripheral vascular collapse. Its use in the emergency or admitting rooms makes possible an immediate assessment of critically ill patients. Since the normal heartbeat causes regular pulsations of the galvanometer needle, the observer is able to discern the onset of ventricular fibrillation by the small, irregular, and highly erratic oscillations lacking regularity of rate and amplitude and of cardiac standstill where the movements of the galvanometer cease. The amplitude of the oscillations is not visibly affected by the profound hypotension of the pulseless patient in peripheral vascular collapse; thus, the differentiation of the latter condition from that of cardiac standstill and ventricular fibrillation is possible without resort to thoracotomy.

An Evaluation of Portacaval Shunts for Portal Hypertension. G. A. Hallenbeck and E. Shocket. Surg. Gynec. & Obst. 105:49-60 (July) 1957 [Chicago].

Portal hypertension occurs in man when the portal system blood flow is impeded either within the liver by cirrhosis or other diseases or outside the liver by diseases of the portal vein and its tributaries. Portal decompression by some form of portacaval anastomosis seemed a natural solution to the problem of bleeding from esophageal varices. Operative technique soon resolved itself about the anastomoses between the portal vein and vena cava (end-to-end and side-to-side) and the splenic and left renal veins (end-to-side). Of the 47 patients, with an age range of 5 to 73 years, 43 had cirrhosis and 44 had experienced hematemesis. Acceptable evidence for a diagnosis of esophageal varices includes positive evidence in the esophagogram or on esophagoscopic examination with a history of bleeding eliminated by esophageal tamponade. Of the 47 operations 29 were direct portacaval shunts (1 side-to-side; 28 end-to-side) and 18 were splenorenal shunts. The hospital mortality of the portacaval shunt was 20.7% and of the splenorenal shunt (accompanied by splenectomy) was 5.6%, with a collective mortality of 14.9%. The hospital mortality rate was a function of and reflected the degree of liver function impairment, lending strength to the belief that patient selection does greatly influence the hospital mortality rate. Although postoperative data are scanty and somewhat inconclusive, portacaval shunts are believed to be more effective in relieving portal pressure than the splenorenal shunts. The difference between portacaval and splenorenal subsequent postoperative bleeding propensity is negligible. The 47 patients experienced a total of 75 hemorrhages during the 12-month preoperative period, while the survivors (40) experienced only 4 hemorrhages during a similar postoperative period. The effect of portacaval shunts on hepatic function is not readily apparent as a transient depression of hepatic function ensues postoperatively. Very few of the patients showed improved hepatic function and a like number showed correspondingly reduced function, the greater portion of the patients remaining unchanged. Neurological symptoms did not appear in any of the 17 patients after splenorenal anastomoses. Varying degrees of neurological symptoms did develop subsequently in 6 of the 23 surviving portacaval shunt patients. A widespread thrombus in the portal system was the cause of the one death in the splenorenal series. More high-risk patients have been subjected to portacaval shunts than to splenorenal shunts. Portal decompression is planned for those who have bled from varices and whose hepatic function has been adjudged adequate to withstand operation.

Postoperative Collapse Due to Adrenal Insufficiency Following Cortisone Therapy. G. Slaney and B. N. Brooke. Lancet 1:1167-1170 (June 8) 1957 [London].

Patients who have received cortisone are liable to collapse when later submitted to the stress of an operation. There is evidence that this state of shock is the outcome of adrenal insufficiency due to atrophic changes within the adrenal cortex induced by corticosteroid therapy. Death in 3 patients could be explained only on these grounds. Shock was successfully treated in 4 other patients by the further administration of cortisone, though one eventually died. Cortisone should be administered prophylactically to any patient undergoing operation who has had corticosteroid therapy within a year, and possibly 2 years, of the operation; cortisone cover should include the operation period and should be withdrawn during convalescence. The suggested dosage for prophylactic treatment is presented in a table. The scheme is based on the fact that cortisone administered orally is most effective from 4 to 8 hours later; intramuscularly, 8 to 12 hours later; and intravenously (as hydrocortisone), almost immediately but only for a short time.

Since the authors have given corticosteroid cover immediately before, during, and after operation, postoperative shock has been conspicuous by its absence in 8 patients severely ill with ulcerative colitis after previous corticoid therapy: 10 operations were performed with uninterrupted recoveries. One of the patients undergoing primary colectomy is of particular interest because, though his blood pressure did not fall after this major operation, it fell after a minor operation undertaken subsequently when cortisone cover had been withdrawn. The complications usually associated with cortisone therapy must be expected while prophylactic cover is being maintained, especially a tendency to infection and septicemia. Such infections require larger doses of antibiotics than usual for their control. In any patient for whom corticosteroid therapy is contemplated, careful consideration should be given to the likelihood of operation being needed. Operative risks are increased by antecedent administration of cortisone.

Functioning and Nonfunctioning Adrenal Cortical Tumors. P. Heinbecker, L. W. O'Neal and L. V. Ackerman. Surg. Gynec. & Obst. 105:21-33 (July) 1957 [Chicago].

There is no constant clinical syndrome associated with adrenal cortical tumor, as the symptomatology is dependent on the type of cortical hormones elaborated by the tumor. Thus, adrenal tumors are less apt to produce a "pure" syndrome than the adrenal hyperplasias. The chief symptoms and findings in Cushing's syndrome are central obesity with acral wasting, profound depression, florid round face, bruising, purplish striae, hypertension, amenorrhea, susceptibility to infection, poor healing of wounds, and back pain, occasionally with collapse of vertebrae. Some 80% of the adrenal tumors producing Cushing's syndrome occur in females, while a larger percentage (76%) of these same cases occur in females over the age of 12. Virilization may result in advanced bone age in children, whereas Cushing's syndrome may be associated with retarded bone age. The diagnosis of virilizing syndromes is confirmed not by abnormalities in blood cell count, carbohydrate metabolism, or plasma electrolytes but by the increased amounts of 17-ketosteroids in the urine due to either tumor or hyperplasia of the adrenal cortex. Allen's test for dehydroisoandrosterone is useful in differentiating tumor from hyperplasia, since patients excreting exceptionally large amounts of dehydroisoandrosterone were all found to have tumors. Polycythemia, leukocytosis with a lymphopenia, and a decrease in circulating eosinophils; a diabetic-type glucose tolerance curve; increased capillary fragility; osteoporosis; and hypokalemic hypochloremic alkalosis have all been found among patients exhibiting Cushing's syndrome. The urinary excretion of 17-ketosteroids and 17-hydroxycorticosteroids are more apt to be higher in Cushing's syndrome due to malignant tumor than in Cushing's syndrome due to adrenal hyperplasia. Further differentiation is possible (1 case observed) in that cortisone will suppress the urinary excretion of 17-ketosteroids in Cushing's syndrome due to adrenal hyperplasia but will not affect that excretion of 17-ketosteroids due to tumor. Pathologically, tumors with fairly regular nuclei but with capsular invasion and invasion of veins are associated with a malignant course. Accessory findings helpful in differentiating benign and malignant tumors are necrosis, calcification, pleomorphism, and nuclear atypia.

The mortality rate following removal of a cortical tumor in Cushing's syndrome was exorbitantly high (56.3%) when substitution therapy was lacking or was inadequate. This rate was reduced to 20.6% due to better replacement therapy. Atrophy of the remaining normal adrenal cortex resulted in postoperative cortical insufficiency with a high mortality rate. Excision of adrenal tumors in the androgenital syndrome is accomplished at a much lower mortality rate than above due to lower incidence of atrophy in the contralateral adrenal cortex. Long-term results following removal of benign tumors are favorable, while the results with malignant tumors are poor, only 1 of 10 patients being alive and well at a 10-month follow-up.

Nitrogen Mustards in Preoperative Treatment of Cancer of Digestive Tract. M. Maur and S. Zampini. Semana méd. 23:759-765 (May 30) 1957 (In Spanish) [Buenos Aires].

The authors used derivatives of dichlorodiethyl sulfide (Yperite) for the alleviation of symptoms of cancer of the digestive tract. Nitrogen mustard was used in the preoperative treatment of 4 patients with advanced cancer of the digestive tract. The first patient treated had a tumor of the stomach about 2 cm. below the cardia, of 1½ years' duration, with increasing dysphagia for 7 months. Dysphagia disappeared after the 7th injection of nitrogen mustard. The second patient presented symptoms of extensive carcinomatous infiltration of the lesser and greater curvatures of the stomach, poor general condition, and severe pain for the past 2 years. Nitrogen mustard treatment brought about disappearance of pain and of dysphagia. The third patient had a palpable tumor in the right iliac fossa, 13 by 6 cm. in diameter; the radiologic examination showed a tumor of the cecum and of the ascending colon. Treatment with nitrogen mustard brought about diminution of the size of tumor by 50% and improvement in the general condition. Nitrogen mustard therapy made possible an easy excision of the tumor in these 3 patients. The 4th patient had a tumor in the pelvis, a small hepatic metastasis, and carcinomatosis involving the posterior and lateral peritoneal surfaces. The first operation brought about only palliative results. The administration of nitrogen mustard permitted a second operation 6 months after the first. The result was satisfactory. The authors believe that nitrogen mustard can be used in the preoperative treatment of all types of cancer considered inoperable on the basis of clinical examination.

Diagnosis and Treatment of Diastematomyelia. G. Perret. Surg. Gynec. & Obst. 105:69-82 (July) 1957 [Chicago].

In the past 2 years 5 verified cases of diastematomyelia were diagnosed and treated at the University Hospital at the University of Iowa. All of these patients presented obvious cutaneous defects, underlying spinal canal defects, and associated neurological disorders. This condition is more frequent in females than males and in infancy and childhood. A bony, cartilaginous, or fibrous septum is a characteristic feature of the malformation. Other symptoms, depending on the extent and location of the malformation, include weakness, atrophy, maldevelopment and malformation, associated disturbances in gait and stance, disturbances in sensation, reflex changes, impaired function of the bladder and rectal sphincter, and secondary infections, ulcerations, and trophic changes of anesthetic areas. In the 5 cases studied a diagnosis of congenital spinal anomaly was made clinically. Further diagnosis of diastematomyelia is contingent upon roentgenologic and myelographic examinations and surgical verification. Cutaneous defects were present in all of the cases; 4 patients had symptoms of hypertrichosis, characterized by long, soft, silky hair lying in the midline of the back over the region of the underlying bony anomaly. In the lumbar and lower thoracic regions the "upward migration" of the cord is impeded by the presence of a bony, fibrous, or cartilaginous malformation of the spine producing considerable tension on the spinal cord proper and ultimately neurological disturbances. Operative technique (via laminectomy) provides for the removal of the cord-transfixing elements and mobilization of the spinal cord and is considered prophylactic rather than curative. Patients so treated have either improved clinically or failed to show progression in their neurological disturbances.

Closing of Atrial Septal Defects with the Aid of Hypothermia. D. E. Thomas. U. S. Armed Forces M. J. 8:784-788 (June) 1957 [Washington, D. C.].

Atrial septal defects are sometimes cribriform, that is, there may be a large defect and several small ones. Operation under direct vision is therefore preferable to the closed methods, because it has the following advantages: (1) more complete closure of the defect, (2) detection and correction of associated anomalies such as pulmonary venous drainage into the right atrium, and (3) protection of the coronary sinus from partial or complete occlusion by a suture. The author reviews observations on 18 patients in whom operations were performed under the guidance of Swan and his group, who have had great experience in interatrial surgery under direct vision during hypothermia. Seventeen of the 18 operations were performed with the aid of hypothermia and 1 with the bubble oxygenator. Ten patients were less than 10 years of age, 4 were 20 to 30, and the remaining 4 were 30 to 38 years of age. In general, there was a history of retarded growth, dyspnea on exertion without cyanosis, and frequent respiratory infections. Lack of cyanosis is to be expected, because the shunt is from let to right. The severity of symptoms varied. The patients were generally underdeveloped and underweight. There was increased vascularity of the lung fields, enlargement of right auricle and ventricle, posterior displacement of the esophagus by the right auricle, and increased pulsation of the pulmonary artery. Electrocardiograms often showed incomplete right bundle-branch block and evidence of right ventricular hypertrophy. Cardiac catheterization revealed evidence of a left-to-right shunt at the atrial level with increased oxygenation of the blood. Mild to marked right ventricular and pulmonary artery hypertension was frequent.

There were 2 deaths in this group of 18 patients. Neither of these deaths was considered to be the result of hypothermia. One was due to bronchopneumonia on the third postoperative day. The other was believed to be due to ventricular fibrillation. Follow-up evaluation was possible in 13 patients. Eleven of these showed weight gain, increased strength and vigor, and unlimited activity. One patient has residual symptoms from peroneal palsy and one, given a preoperative diagnosis of psychogenic musculoskeletal disorder without true cardiovascular symptoms, reports no postoperative improvement. Air embolism has not been a problem, because the left side of the heart was flooded with isotonic sodium chloride solution through the defect just prior to the tying of the last suture. The right auricle and ventricle are similarly flooded prior to the clamping off of the incision in the auricular wall. The coronary arteries are protected from air embolism by placement of the clamp that occludes the aorta and pulmonary artery low enough to occlude the coronary ostia. Ventricular fibrillation has been a problem, but not an insurmountable one.

Diagnosis and Surgical Treatment of Mitral Stenosis. F. G. Uglov. Khirurgiya 33:55-60 (No. 5) 1957 (In Russian) [Moscow].

In the surgical treatment of mitral stenosis the differentiation between stenosis and insufficiency plays an important part. Among the 100 patients with a clinical picture of mitral stenosis operated on, there were 9 exhibiting mitral insufficiency, the atrioventricular orifice admitting 1½ to 2 fingers. There was 1 fatality in this group of 9; the remaining 8 did well and were much improved. Analysis of the 100 patients studied clinically and operated on suggests the following factors as favoring the diagnosis of stenosis: pulmonary stasis, insignificant or no enlargement of the left ventricle, and absence of prominence of the aortic arch as compared with that of the pulmonary artery in the roentgenogram. Electrocardiographic data pointing to hypertrophy of the ventricles are of diagnostic importance. Data suggesting hypertrophy of the left ventricle speak for the predominance of insufficiency. Pronounced dyspnea on mild exertion and pain in the cardiac area in the absence of ascites or markedly enlarged liver speak for stenosis, while patients with aortic insufficiency have less dyspnea on exertion in the presence of liver enlargement and even of ascites. The above signs and symptoms have only relative value in the differential diagnosis between stenosis and insufficiency. Operative intervention is indicated in the doubtful cases as well. Diagnosis of mitral stenosis constitutes an absolute indication for surgical intervention, provided the patient is not in the stage of severe and irreversible decompensation. Among the 100 patients operated on there were 11 fatalities. Commissurotomy improves the general condition of the patients to a greater extent. The operation is equally effective in the presence of auricular flutter and moderate decompensation.

Coronary Endarterectomy: Curettement of Coronary Arteries in Dogs. A. M. May. Am. J. Surg. 93:969-673 (June) 1957 [New York].

Instrumental exploration of the coronary arterial tree, both through a transaortic approach and by an approach through the terminal portion of the coronary arteries, was successfully accomplished in 23 adult dogs of various size. Injuries to the intima of the coronary artery may be produced without causing death or disability of the animals. Previous to animal experimentation, curette procedures were carried out on 18 human cadavers; it was found feasible to remove the atheromatous tissue from the first portion of the coronary arteries. Techniques and approaches are described. The retrograde method was found the most practical and quickest, involving minimal mortality.

Experiences with Extracorporeal Circulation in Open Cardiac Surgery. G. H. Pratt. Am. J. Surg. 93:960-969 (June) 1957 [New York].

Lesions of the heart were treated surgically in 3 ways. Closed-heart surgery does not require direct vision of the inside of the heart. The open-heart technique with hypothermia imposes a strict time limit. The cardiopulmonary bypass with a pump oxygenator is the third method of heart surgery. The author emphasizes the difficulties and the time and effort one must expend to master the open-heart surgery technique. The technical points that have to be surmounted in performing successfully heart-lung work, requiring much experience, are detailed. A well-trained team, experienced in all types of major and thoracic surgery, with the cooperation of the departments of pathology and hematology, worked with a partial oxygenation pump and performed 2 and 3 operations a week for 5 months before a dog survived the surgery. Success had to be achieved on dogs before operation on human beings were attempted, since these animals are difficult to keep alive after open-heart surgery. Lesions of the heart, previously not corrected or only partly helped, such as ventricular septal defects, atrioventricularis communis, isolated infundibular pulmonary stenosis, and the tetralogy and pentology of Fallot, have been operated on successfully. No clinic should undertake open-heart surgery until routine success on experimental animals can be demonstrated.

The Surgical Treatment of Chronic Pancreatitis. R. F. Bowers. J. Kentucky M. A. 55:511-516 (June) 1957 [Louisville].

A plan of therapy for chronic pancreatitis is presented. Biliary surgery, choledochojejunostomy en Roux Y, and cystenterostomy or cystgastrostomy gave excellent results in selected patients when performed in the early stages of the disease. Control of the attacks of pancreatitis was achieved in half of the patients by biliary tract surgery alone. Choledochojejunostomy en Roux Y was performed when attacks recurred and no disease of the biliary tract could be demonstrated. Of 19 patients thus operated on, only 1 was designated as a failure; he developed a pseudocyst. No satisfactory procedure for control of the disease was found when the "burning out" or "burned out" stage of the disease was reached. A few patients might be helped by caudal pancreaticojejunostomy. The only relief in this stage was obtained by pancreaticoduodenectomy, but the disadvantage of this procedure is the formation of peptic ulcers, caused by the loss of the alkaline pancreatic secretions to the duodenum.

Rheumatoid Arthritis Presenting as Tenosynovitis. J. H. Jacobs, E. V. Hess and I. P. Beswick. J. Bone & Joint Surg. 39B:288-292 (May) 1957 [London].

Tenosynovitis with effusion has often been considered of tuberculous origin, but many cases have been reported in which conclusive evidence of tuberculosis was not found. While it is well known that tendons and tendon sheaths may be involved in the course of rheumatoid arthritis, it is not so widely recognized that early rheumatoid arthritis may present as isolated attacks of tenosynovitis. The authors present the histories of 3 women, aged 41, 42, and 68 years, respectively, in whom tenosynovitis of the hands and wrists was the primary manifestation of rheumatoid arthritis. Involvement of the joints first became apparent 18 months, 14 months, and 4 months after the preceding attacks of tenosynovitis. One of these patients had 2 attacks of tenosynovitis, one involving the right and other the left hand, before the development of arthritis. It is often impossible to distinguish, on clinical grounds, between tuberculous tenosynovitis and isolated rheumatoid tenosynovitis. The appearance of the tendons and sheaths at surgical exploration still leave the diagnosis in doubt, and it is not the tendon sheaths have been examined histologically that the true nature of the condition becomes apparent.

The biopsies taken from the 3 patients showed hyperemia and edema of the tendon sheaths, proliferation of synovial lining cells with exudation of fibrin upon synovial surfaces, and diffuse infiltration of the tissues with lymphocytes and plasma cells, together with the formation of circumscribed lymphoid nodules. While no single one of the changes seen in the tendon sheaths in these patients can be considered specific of rheumatoid arthritis, collectively they provide strong presumptive evidence of the diagnosis.

The Secretory and Clinical Aspects of Achlorhydria and Gastric Atrophy as Precursors of Gastric Cancer. C. R. Hitchcock, L. D. MacLean and W. A. Sullivan. J. Nat. Cancer Inst. 18:795-809 (June) 1957 [Washington, D. C.].

At the University of Minnesota Hospitals, screening for achlorhydria and hypochlorhydria has proved an effective means of diagnosing a reasonable number of gastric cancers in the asymptomatic phase of the disease. During a 10½-year period, over 12,000 men an women have undergone a screening test to detec those persons likely to develop gastric cancer. Th portion of the total population that must be examine periodically because of increased likelihood to develop gastric cancer has been reduced to 6½%. Th problem of population screening becomes economically feasible through this method, and adequate protection for the population at large appears to result fro this approach. No case of gastric cancer in the University of Minnesota Cancer Detection Research Center would have been undetected if all other screenin techniques except examination for achlorhydria an hypochlorhydria had been omitted. The etiologic relationship of achlorhydria and atrophic gastritis wit gastric cancer is strongly supported by these result In the achlorhydric-hypochlorhydric group the incidence of gastric cancer is 4.5 times greater and in th pernicious anemia group 21.9 times greater than i the same segment of the normal population. Thes studies indicate that in pernicious anemia patien gastrointestinal roentgenograms should be made 6-month intervals and in patients with achlorhydria hypochlorhydria at 9-to-12-month intervals. Addition studies of achlorhydric persons, by means of th Schilling test, indicate that about 5% have preclinic pernicious anemia. Further refinement of the grou that require repeated study may be possible throu the application of tests of this kind.

Resection in Pulmonary Tuberculosis. B. Gontijo. Re brasil. tuberc. 25:697-706 (May) 1957 (In Portugues [Rio de Janeiro].

The author considers resection a better treatme than su [illegible] l collapse therapy in the treatment [illegible] berculosis. His experience is based

105 patients, who were subjected to pulmonary resection between January, 1949, and May, 1954. Thirty-seven of these had a pneumonectomy, 60 a lobectomy, and 8 a segmental resection. There were 22 instances of postoperative complications. They were, in order of importance, bronchial fistula, dissemination of the process, focus reactivation, empyema without a fistula, and reopening of cavity. Eleven of the 105 patients died. Six deaths were related to the operation proper or took place within a month after the operation. The causes of death were surgical shock in 2, dissemination in 3, and embolism in 1. Five deaths occurred later, all due to a bronchial fistula. Deaths due to surgical shock deserve special mention. The author contends that this was probably due to maladministration of anesthesia, because later, when the technique of anesthesia was improved, no death occurred due to surgical shock. The author considers anesthesia as the most important factor of success in pulmonary resection. The clinical course upon discharge from the hospital was satisfactory. There are also economic and social advantages in pulmonary resection: shorter period of hospital confinement, quicker and better readjustment to normal life, and less physical deformity than after a thoracoplasty.

Thymic Cyst in the Neck: Case Report. A. S. Crawford, P. V. Evans and W. Thompson. J. Indiana M. A. 50:715-719 (June) 1957 [Indianapolis].

The authors present the history of a 6-year-old boy who had a swelling of 3 years' duration on the right side of the neck. It had existed without symptoms, and was noticed by the parents only when he laughed or cried. About 6 weeks prior to admission the mass began to enlarge, and it became painful on palpation. It had not interfered with eating or swallowing. The cystic mass was lateral to the thyroid; it appeared to be well demarcated from the adjacent structures and was freely movable; it was estimated to be 4 to 5 cm. in diameter and was moderately tender to palpation; it extended laterally to the anterior border of the right sternomastoid muscle. At operation the cyst was found to extend above the right sternomastoid muscle and above the superior thyroid vessels. It was removed by blunt and sharp dissection. The lower portion of the cyst extended into the superior mediastinum. When the cyst was accidentally ruptured during dissection it yielded a thick, brown-red fluid. At this time it was noted that the surrounding tissue had the appearance of thymic tissue. The histological examination revealed thymic tissue in all examined sections of the wall of the cyst.

The authors cite evidence indicating that thymic cysts occur in the neck more frequently than the literature suggests. The case presented proves the advisability of including a posteroanterior roentgenogram in the routine investigation of cystic lesions in the neck. The possibility of malignancy of thymic tissue should be a consideration in lesions of the type under discussion. Two cases of malignancy in aberrant thymus tissue were reviewed, 1 of which was observed in an 11-year-old child and the other in a 58-year-old adult. That in the child was located in the neck.

Giant Chondroma of Maxilla Making Necessary Hemifacial Removal of Tumor with Enucleation of the Eye. A. García Blanco and E. Planas García de Dios. Rev. espān. oto-neuro-oftal. 14:130-134 (March-April) 1957 (In Spanish) [Valencia, Spain].

Giant chondroma of the maxilla is extremely rare. A 34-year-old woman complained of respiratory difficulty, eye symptoms, and headache of 1 year's duration. An enormous exophthalmos of the left eye caused lacrimation, loss of vision, and pain over the eye and the supraorbital region. Roentgen therapy in two series of 14 and 36 sessions, respectively, did not bring relief. Roentgen examination of the head showed a tumor which occupied the entire left ethmoido-orbital region. Biopsy demonstrated a chondroma. An operation was performed with the patient under general anesthesia with intubation. The tumor included the entire left ethmoidal and orbital regions, the eye, the septum, and the right turbinate bones. The tumor was extirpated with an electric knife, and the eye was enucleated. The patient was given 300 cc. of blood during the operation. Antibiotics were given in the immediate postoperative period. Histopathological examination of the tumor confirmed the diagnosis of a chondroma. The postoperative period was uneventful. The patient was discharged 1 month after the operation. She was requested to report in 2 months for a plastic repair of the mutilated region.

NEUROLOGY & PSYCHIATRY

Prognosis in Hemiballismus. H. H. Hyland and D. M. Forman. Neurology 7:381-391 (June) 1957 [Minneapolis].

The occurrence of hemiballism is reported in 6 women and 8 men between the ages of 26 and 84 years. In one 26-year-old man the condition became manifest after a cerebral trauma caused by a severe blow on the left temporal region. Hemiballism developed in a 42-year-old man at the time of an exacerbation of multiple sclerosis of 17 years' duration. The hemiballism was considered to be a result of cerebrovascular disease in the remaining 12 patients, whose average age was 72 years. In great contrast to the generally accepted unfavorable prognosis, spontaneous recovery occurred in 12 patients. Four patients had hypertension and 2 had diabetes mellitus. In several patients there was evidence of myocardial disease and/or diffuse cerebrovascular disease. The rapidly executed extensive involuntary movements of the limbs of one-half of the body which characterized the clinical picture lessened in severity after 1 to 3 weeks and usually subsided completely during the next 4 to

9 weeks. There was only 1 patient in whom cessation of the hyperkinesis was rather abrupt, occurring 5 days after the onset. This patient had a number of cerebral softenings caused by cardiac emboli, including that which had destroyed the subthalamic nucleus. It was thought possible that another vascular lesion may have involved other pathways and in some manner offset the effect of the damage to the subthalamic nucleus, thus causing the hemiballism to stop.

Treatment consisted of good nursing care combined with the use of hypnotic drugs in most of the 12 patients in whom the hemiballism subsided spontaneously. The prompt relief of symptoms in 2 patients who were given chlorpromazine suggested that this drug had a specific effect in controlling the hemiballism, but it was ineffective in 1 other patient. One of the 2 patients in whom hemiballism failed to subside spontaneously died with the disorder, and the other would probably have died had cerebral pedunculotomy not been performed successfully. It is suggested that spontaneous recovery from hemiballism is more likely to take place if the lesion involves the afferent connections of the subthalamic nucleus and the latter escapes destruction. There was evidence in 4 patients that this had occurred. Autopsy revealed the lesion in this situation in 1 patient who died 2 months after recovery from hemiballism. There were 3 other patients with spontaneous recovery who had signs of thalamic involvement occurring simultaneously with the hemiballism. The occurrence of these manifestations together makes it seem probable that hemiballism was caused by damage to the afferent connections rather than the subthalamic nucleus itself. The results obtained in the patients suggest that many will recover with conservative measures alone. Neurosurgery should be necessary only in patients with a long unremitting course or in whom deterioration due to exhaustion renders it essential.

Some Neurological Aspects of Epilepsy: Analysis of 407 Cases of Epilepsy from the Clinical and Etiological Point of View. I. Alfandary. Harefuah 52:283-288 (June 2) 1957 (In Hebrew with English Summary) [Tel Aviv, Israel].

Of 407 patients with epilepsy who were studied in an attempt to determine its cause, it was not possible to do so in 138 patients (33.9%). However, 34 (25.3%) of the 138 patients showed other signs of involvement of the central nervous system or of delayed mental development; consequently an organic origin, most often obstetric trauma, seemed to be likely. Cryptogenetic or idiopathic epilepsy was suspected in only 33 (8.2%) of the patients. Several causative factors may often be present in the same patient, such as obstetric trauma or accidental trauma and heredity or migraine. It may be difficult to decide which of these causes could be the decisive factor.

Birth or accidental trauma were the 2 main causes identified in 122 patients (30%). Next in order were cerebromeningeal infection and tumor. Heredity is not a common cause, since it was identified in only 37 patients (9%). Cases with similar heredity were not always of central encephalic type. In 2 cases, the father had late epilepsy of cortical type and the child had early epilepsy either of cortical or of central encephalic type. These findings confirm the importance of a predisposing factor. Tonic and akinetic types of seizures occurred in children with serious brain damage, especially lesions of the brain stem. A satisfactory explanation of the "paralytic," inhibitory, or negative seizures is still lacking. These convulsive attacks are manifested by paralysis of one or several extremities, absence of feeling of a part of the body, hemianopsia or scotoma, arrested thinking, or a sensation of empty stomach. Inability to understand words or to utter them most probably belongs to the same group. Succession of a negative hallucination after a positive one of the same type is noteworthy. The anatomic and psychic types of auras were observed most frequently. The various forms of partial seizures are discussed with regard to, differences in the auras. Psychomotor epilepsy is not a homogeneous group with regard to clinical aspect and anatomic and electroencephalic findings. It might be classified with the focal forms of epilepsy, although its identification with temporal epilepsy does not seem to be entirely justified.

Protection Against Reserpine-Induced "Parkinsonism." H. A. Rashkis and E. R. Smarr. Am. J. Psychiat. 113:1116 (June) 1957 [Baltimore].

When 24 schizophrenic patients were given reserpine, either alone or in combination with other drugs, 9 developed the characteristic Parkinsonism-like syndrome. Twelve patients received reserpine alone, 12 patients trihexyphenidyl alone, and 24 patients reserpine in combination with trihexyphenidyl. It was found that giving trihexyphenidyl with reserpine afforded protection against the development of a Parkinsonism-like syndrome. In view of this finding it has become their practice, whenever prescribing reserpine in large doses, to initiate therapy with trihexyphenidyl immediately instead of waiting for a Parkinsonism-like syndrome to develop.

Congenital Syphilis as a Cause of Mental Deficiency. C. B. Courville. Bull. Los Angeles Neurol. Soc. 22:85-90 (June) 1957 [Los Angeles].

The history and autopsy report of a Negro girl who died at the age of 9 years as the result of tetanus is presented. She had sustained an abrasion of the left knee while playing in a freshly fertilized flower bed. The child had been mentally defective since birth and was spastic. The Wassermann test on blood from the umbilical cord had been strongly positive at birth, but no symptoms were noted until the child was 9 months of age, when strabismus became apparent. A retarded mental state was noted later. She had made fair progress in school for retarded children. Autopsy was performed, and death was considered to be due to tetanus. The brain was examined in a neurological laboratory. There was an atypical basilar artery and vascular anomaly of the left cerebellar hemisphere; widespread increased pial vasculature; perivascular lymphocytic accumulations; and diffuse and patchy loss of cortical nerve cells. Mental deficiency as well as cerebral palsy was the apparent result of congenital syphilis.

The presence of marked perivascular round cell accumulations in the cerebral cortex of a 9-year-old girl indicates a continued effect of the syphilis from the intrauterine period to the time of her death. This effect was exerted very likely through the medium of the circulation, as suggested by the predominant loss of nerve cells in the upper cortical layers, which ordinarily have an abundant blood supply. This is not difficult to understand, since syphilis is primarily a vascular disease. The absence of notable structural changes in the cortical arteries also suggests that this circulatory disturbance was probably functional in nature. In the past, congenital syphilis played a significant role in the production of mental deficiency. The incidence averaged approximately 6% in the period ending about 1935. In the past 20 years, it has dropped to about 4%. It is to be anticipated that in the future syphilis will play a decreasing role in the causation of mental deficiency, thanks to the efficiency of antibiotic therapy. The pathological changes found in the central nervous system in those who die in childhood or early adolescence are syphilitic meningitis, syphilitic vascular disease (including endarteritis), or congenital paresis. In those who die after the age of 16 years, chronic meningovascular syphilis is more likely to be present, the chronic meningeal or meningovascular form being less likely to bring about a fatal issue.

Arterial Hypertension in Poliomyelitis. E. Kemp. Acta med. scandinav. 157:109-118 (No. 2) 1957 (In English) [Stockholm].

This report is based on experience gained in Blegdamshospitalet in Copenhagen during an epidemic of poliomyelitis in Denmark in 1952. Frequent blood pressure measurements proved valuable in discovering imminent or existing hypercapnia or hypoxia. Some patients had acute kidney lesions, which probably caused hypertension. In other patients, however, who apparently were well-ventilated and without kidney lesions, hypertension developed and occasionally persisted in spite of marked clinical symptoms of shock. An attempt was made to elucidate whether the hypertension in these patients was due to lesions in the central nervous system. The blood pressure was measured in 337 patients with poliomyelitis; this number included some from an earlier epidemic. The development of hypertension during poliomyelitis was influenced by neither the age nor the sex of the patient; it occurred with equal frequency in children and adults and in males and females. Hypertension persisting for days was observed during the acute stage of poliomyelitis in 55% of the patients who died; in 30% of those with bulbar, 45% of those with the bulbospinal, and in 40% of those with severe spinal forms of poliomyelitis. Neither artificial ventilation nor hypoventilation or hyperventilation seemed necessary or sufficient causes for the development of hypertension persisting for days in poliomyelitis patients treated with present-day methods. Azotemia, or changes in the spinal medulla, in the diencephalon, or the telencephalon likewise did not seem to play a part. Observations in the course of the present study suggested, however, that ganglionic cell degeneration in the nucleus magnocellularis in the medulla oblongata is a necessary condition for the development of hypertension.

Changes in the Nervous System in Acute Porphyria. R. Hierons. Brain 80:176-192 (June) 1957 [London].

The author describes studies on the nervous system of 5 patients with acute porphyria and discusses the findings in relation to the clinical features of the disease. Abnormalities were present in the anterior horn cells of the spinal cord in all of these patients. Chromatolysis was clearly secondary to axonal damage. It seems extremely unlikely that axonal damage can explain the vacuolation of the cytoplasm in some of the neurons and also the presence of shrunken cells. It is suggested that vacuolation is a stage in cell loss. Material from the peripheral nerves was available in 3 of the patients. The peripheral nerve lesions probably result from a metabolic disturbance and not from a vascular spasm. The neuronal changes in the anterior horn cells are probably also of metabolic origin. Extensive vascular lesions were observed in the brain, but these were probably secondary to severe hypertension or respiratory paralysis and were not the cause of the severe mental disturbance. The mental disturbances are probably due to a direct, possibly reversible, metabolic effect of the disease; and this may result in some loss of neurons in the brain and cerebellum similar to that in the spinal cord.

Brain-Stem Encephalitis. E. R. Bickerstaff. Brit. M. J. 1:1384-1387 (June 15) 1957 [London].

A syndrome of brain-stem encephalitis not previously described in the literature, involving a prodromal period of general malaise and mild pyrexia, gradual signs of midbrain disturbances, and no cardiac and respiratory embarrassment, is reported in connection with the observation of 4 additional cases. No significant connotation is accorded age, sex, and geography in the classification and description of early signs and symptoms. The period of onset was gradual, lasting from 1 to 3 weeks and featuring general malaise, drowsiness, headache, and some muscular aching. Early symptomatology included mild headache, marked drowsiness, double vision, vomiting, ptosis, defective conjugate eye movements, dysarthria, unsteadiness of gait, and low-grade pyrexia. Progress from onset to maximal disability ranged from 1 to 8 weeks, while further progress to total recovery varied from 1 to 17 months. At the point of maximal disability there was partial to complete ophthalmoplegia, bilateral paralysis of the motor branch of the trigeminal nerve, total bilateral facial paralysis, deafness, gross paralysis of the 9th, 10th, 11th, and 12th cranial nerves, complete anarthria, and loss of tendon reflexes except plantar extensor response. During the stage of return of neurological function some of the patients developed an extrapyramidal type of rigidity and others a Parkinsonian tremor or emotional lability. These more recent developments disappeared shortly after they appeared. It is significant that neurological recovery has been complete in all the cases observed save 1, with the exception that intellectual deficit occurred in one patient to the extent that it interfered with his education. The outstanding feature of these cases is the dramatic total recovery after subacute development of disturbed brain-stem function so gross that at one stage survival even for a few days seemed impossible.

Rehabilitation of 250 Patients with Chronic Sequels of Acute Poliomyelitis by Intra-arterial Growth Hormone Treatment. E. Henriquez, A. Bueno García, J. Pérez Alama and others. Rev. med. hosp. gen. 20:321-329 (May) 1957 (In Spanish) [Mexico, D. F., Mexico].

The authors have previously reported satisfactory results from the administration of intra-arterial injections of growth hormone in treatment of chronic sequels of acute poliomyelitis (abstracted in THE JOURNAL [162:1665-1666 (Dec. 29) 1956]). Results in 250 patients who had a follow-up of more than 1 year are reported in this article. The patients were of both sexes and were between the ages of 1 and 27 years. Sequels had lasted between 6 months and 25 years prior to the treatment. The drug was given in doses of from 1 to 3 cc. in 1.5 cc. of saline solution for each injection. The injections were made into the femoral artery for sequels in the legs or into the subclavian artery for sequels in the arms. They were given once a week to a total of 3 to 8 injections for each limb treated. The following results were observed: The treated limb increased in size at an average monthly rate of 0.5 to 1 cm. in 145 cases. It did not change in 5 patients. The muscles increased in thickness at an average monthly rate of 0.5 to 1.5 cm. Muscular movement, muscular tonicity, local temperature of the skin, and the patellar, plantar, and achilles reflexes appeared or increased in almost all of the cases. Complete recuperation (100%) was obtained from complete functional incapacity (100%) in 39 cases, from moderate incapacity (50%) in 58 patients and from marked incapacity (75%) in 107 patients. Marked functional capacity (75%) from marked functional incapacity (75%) was obtained in 46 patients. In the course of the treatment transient hyperglycemia was observed in 2 cases, lowering of the erythrocyte count in 2 cases, and an acute headache in 2 cases. These disturbances were controlled by diminishing the dose of the growth hormone. Roentgen examination of the bones showed increase of thickness and of the length of the bone and improvement of osteoporosis. The muscular reactions to faradic and galvanic currents and the chronaxia of the muscles increased. The improvement obtained had not changed 1 year after completion of the treatment. Regression of the sequels did not occur. The authors conclude that the intra-arterial injections of growth hormone secures cure or great improvement of the chronic sequels of poliomyelitis.

Early Symptoms of Multiple Sclerosis: A Survey of Eighty-Two Cases. C. H. Imes. Bull. Los Angeles Neurol. Soc. 22:91-94 (June) 1957 [Los Angeles].

This study was undertaken to discover what the early symptoms of multiple sclerosis had been in patients seen in a Los Angeles Hospital during the years between 1933 and 1951, in order to determine whether a benign climate like that of southern California would alter the course of this disease, especially during its early phase. The fact that some of these patients had moved to southern California after the onset of the disease modifies the figures somewhat. The records of 82 patients in whom the diagnosis was reasonably assured were studied. Sixty-five per cent of the patients had only 1 symptom at the onset, whereas the other 35% had 2 or more symptoms. A survey showed that 29% had visual symptoms and 33% had symptoms of the motor system, 29% had sensory symptoms and 33% had symptoms affecting coordination. Speech was affected early in 2 patients; the sphincters in 8 patients; and 1 patient had progressive fatigue. Other reports had revealed a similar incidence of early symptoms. The time interval between first onset and the consultation on which this survey is based indicated a more benign course extended over a longer period of years for patients in this mild climate than in those living in more severe climates.

GYNECOLOGY & OBSTETRICS

Identification of and Therapy for Vaginal Candidiasis. H. L. Pickhardt and J. L. Breen. Am. J. Obst. & Gynec. 74:42-46 (July) 1957 [St. Louis].

In 23 obstetric patients and in 50 gynecologic patients with symptoms of a vaginal infestation, such as malodorous vaginal discharge, itching, burning, and general discomfort, particularly on walking, a specimen was removed from the posterior fornix or lesions along the vaginal wall with a sterile, cotton-tipped applicator and cultures were made on Nickerson's medium. Cultures positive for Candida were obtained from the specimens of 19 of the 23 obstetric patients and of 35 of the 50 gynecologic patients. The clinical impression of vaginal candidiasis was thus confirmed in 82.6% of the obstetric patients and in 70% of the gynecologic patients. Clinical diagnosis of candidiasis based on symptomatology and physical findings is not perfect, and cultures should be used to support the impression.

Nineteen obstetric and 35 gynecologic patients with cultures positive for Candida were treated for 2 weeks by inserting one applicatorful of a new gentian violet cream intravaginally at bedtime. Six obstetric patients and 2 gynecologic patients were lost to follow-up. Of the remaining 13 obstetric patients, 10 had 1 course of treatment and 3 had 2. Of the 32 gynecologic patients, 22 had 1 course of treatment, 6 had 2, 4 had 3, 1 had 4, and 1 had more than 4. An almost complete culture cure was obtained with a maximum of 2 courses of therapy in the obstetric patients. Similarly, the over-all culture cure in the gynecologic patients was practically ideal, but repeated courses of therapy were required in 11 patients, and 1 patient remained culture-positive after 5 courses of therapy. The gentian violet cream thus has been shown to be an ideal medical therapeutic agent for patients with proved candidiasis. Associated vaginal infections with Trichomonas vaginalis persisting after the eradication of Candida were found in 3 obstetric and 7 gynecologic patients.

Prophylaxis and Therapy of Postoperative Thromboembolism. H. Wimhöfer. Medizinische No. 24, pp. 900-903 (June 15) 1957 (In German) [Stuttgart, Germany].

According to Wimhöfer there are 3 methods of prophylaxis of thromboembolism in women undergoing laparotomy. First, the surgeon should watch for the type of patient with a tendency to thrombosis, characterized by constitutional peculiarities, age, poor circulation, and varicose veins. Certain primary disease and certain operations favor the occurrence of thromboembolism. Second, one should watch for prodromal symptoms, such as pain in the calf occurring either spontaneously or being elicited by pressure, pain associated with dorsiflexion of the foot (Homan's sign), and pressure pain in the sole of the foot (Payr's sign). Unexplained acceleration of the pulse and rise in temperature and the absence of postoperative normalization may also be included in this symptomatology. Of 1,506 women who underwent laparotomy at the gynecologic clinic of the University of Heidelberg, Germany, 225 were suspected to be threatened by thromboembolism depending on the criteria listed above. Of the 225 patients, 7.1% had thromboembolism and 4.9% had infarctions. Of the 1,281 patients, 1.5% had thromboses and 0.62% had infarctions. The data show that these 2 methods of selecting patients for prophylactic treatment of thromboembolism are not entirely satisfactory.

The third method of selecting patients for prophylactic treatment of thromboembolism consists of the application of the more recent knowledge of the physiology and pathology of the coagulation of the blood. Hartert's recalcification test performed with the aid of the thromboelastograph provides a more satisfactory result than the Quick test. Of 2,176 women who were subjected to this test, 1,048 did not show signs of a disturbance of coagulation; thrombosis occurred in 1, mild infarction in 2, and fatal embolism in 1 of these, 768 patients had a shortened coagulation time and were given prophylactic treatment; of these, 2 had mild thrombosis, 17 had mild infarction, and 2 had severe infarction. There was no fatal embolism. Early recognition and early institution of treatment prevented the development of thrombosis and the development of large and fatal embolism. Of 45,348 obstetric and gynecologic patients operated on between 1933 and 1950, thromboembolism occurred in 1.21% and fatal embolism in 0.17%. Of 13,288 women operated on between 1951 and 1954, the period during which properly directed prophylaxis was practiced by making use of all 3 methods of selection of patients for anticoagulant therapy, 1,388 were treated with 3-(1-phenylpropyl)-4-hydroxycoumarin (Marcoumar). The rate of thromboembolism among these patients was reduced to 0.32%. Fatal embolism occurred only in patients who had not received prophylactic treatment, and its incidence was 0.023%.

PEDIATRICS

A Case of Phenylketonuria with Borderline Intelligence. D. Y-Y. Hsia, W. E. Knox and R. S. Paine. A. M. A. J. Dis. Child. 94:33-39 (July) 1957 [Chicago].

Phenylketonuria is a congenital inborn error of metabolism associated with mental deficiency in which loss of enzyme activity predisposes to an inability to convert (oxidize) phenylalanine to tyrosine.

This condition is clinically manifested by large amounts of phenylpyruvic acid in the urine and high fasting plasma phenylalanine levels. An otherwise typical case of phenylketonuria in a child with near normal intelligence has been carefully documented. The existence of such cases has been reported (phenylketonuria with near normal intelligence), but none have been established. The patient was one of 2 sisters with similar biochemical disturbances, one of whom is severely retarded (IQ 4) and the other only mildly affected (IQ 78) and able to move about in society. Phenyllactic acid, o-hydroxyphenylacetic acid, indoleacetic acid, and phenylacetylglutamine were present in the urine in amounts usually found in phenylketonuria. Normal heterozygote carriers had plasma phenylalanine levels twice those of normal persons (0.21-0.50) after an oral dose of L-phenylalanine, while the phenylalanine level of the phenylketonurics was zero. From these data the parents and the brother were found to be heterozygous and the patient and her sister homozygous. Thus, this typical homozygous form of phenylketonuria may be associated with borderline intelligence. The existence of such cases showing unusual mental development points to the possible future discovery of new avenues of therapy in addition to the prevention of high plasma phenylalanine levels by the use of low-phenylalanine diets.

Gastroschisis: Report of a Case. W. B. Kiesewetter. A. M. A. Arch. Surg. 75:28-30 (July) 1957 [Chicago].

Gastroschisis is a congenital deformity, peculiar to lower animals as well as humans, in which the abdomen remains open. A possible explanation of this condition is that there is an abnormality of the somites forming the anterior abdominal wall which permits faulty development of a portion of the wall, resulting in a herniation through this defect. The umbilical cord development is normal, as the defect is extraumbilical, but not infrequently there is a complete absence of a peritoneal sac, resulting in marked enlargement and thickening of the intestines. This is the 10th case reported; in 2 cases there were successful surgical corrections. Excision of a black, gangrenous intestine protruding from an aperture to the right of the umbilicus and removal of the narrow orifice through the anterior abdominal wall was followed by a jejunotransversecolostomy. The immediate postoperative course was excellent, considering the minimal intestinal surface area available for absorption. The terminal series of events was characterized by an increasing number of stools with a concomitant weight loss. This case is unique in that a live-born child with this deformity presented strangulation of the intestine due to narrowing of the abdominal wall defect, something that other reported cases did not present.

Results of BCG Vaccination of the Newborn: Observations on the Exposure to and Development of Tuberculosis in 76 Children Vaccinated with BCG at Birth. P. Dannenbaum and A. Bingel. Deutsche med. Wchnschr. 82:919-921 (June 7) 1957 (In German) [Stuttgart, Germany].

At the immunization center of the Municipal Children's Clinic of the city of Braunschweig about 95% of the newborn infants are being immunized against tuberculosis with BCG vaccine; 19,000 newborn infants were subjected to this vaccination in the years between 1949 and 1955. Provided a correct technique is employed, the newborn infants tolerate the BCG vaccine exceptionally well; in only 2 or 3% was there a discharge from the site of vaccination, and ulcers of more than 5 mm. in diameter were rare. Abscess formation of the inguinal lymph nodes was practically never observed. Intracutaneous tuberculin tests (1:100) showed that 95% of the infants achieved tuberculin allergy within 12 weeks. The authors gave special attention to the infants who were exposed to tuberculosis in their environment. When investigation revealed that a person with tuberculosis lived in the same house or camp with the infant but did not belong to the family or that a person within the infant's family had a noncontagious form of tuberculosis, the infant remained at home, but the parents were given strict instructions that, until the tuberculin test had demonstrated that the child had become immune, the child must be protected against exposure; this is relatively easy at this early age. These infants were given special supervision by the immunization center (repeated roentgenologic controls). Tuberculosis did not develop in any of the 248 vaccinated infants.

If a source of infection was known within the family group, the newborn infant was vaccinated with BCG and kept in a children's home until the vaccination had taken effect (proved by a test), after which the child was returned to the parents. Infants whose mothers had open tuberculosis were treated in the same way, provided the infant could be immediately separated from its mother. When this proved impossible, and no matter how short the exposure, the infant was isolated at the clinic for from 6 to 8 weeks, and, if the tuberculin test (1:100) then proved negative, BCG vaccination was carried out; this was followed by another period of isolation until allergy to tuberculin could be demonstrated, and after that the child was returned to its home. The authors studied 76 children who after BCG vaccination during the newborn period grew up in families in which they were exposed to tuberculous infection. The period of observation ranged from 1 to 5 years. Tuberculosis did not develop in any of these children. During this same period 118 children of the same age group were referred to the center for tuberculous children, the diagnosis of tuberculosis being established by tests and roentgenologic examinations. None of these 118 children had received BCG vaccine. The social and economic status was about the same in the vaccinated and in the nonvaccinated children. During the same 6-year period the authors received reports of 20 children in whom tuberculosis seemed to have developed despite BCG vaccination during the newborn period. In 14 of these children the presence of tuberculosis could not be established, and further studies disclosed such disorders as atypical pneumonia, changes in the hilus region, enlargement of the thymus, and pneumonic lesions resulting from whooping cough. The active tuberculosis in the other 6 children could not be ascribed to failure of BCG vaccination because the infant had been continuously exposed to open tuberculosis since birth and had become infected during the preallergic phase.

Wilms' Tumor: Three Cases. C. P. Teixeira. Rev. brasil cir. 33:369-378 (April) 1957 (In Portuguese) [*Rio* de Janeiro].

The author reports three cases of Wilms' tumor in children 2½, 1½, and 1 year old. Two were boys and one a girl. The tumor appeared 8, 6, and 3 months, respectively, prior to the consultation. It was located in the right kidney in all 3. The diagnosis was made on the clinical symptoms and the results of pyelography. It was observed during the operation that the tumor grew toward the abdomen and displaced the liver and intra-abdominal structures to the left. The removed tumors from the boys weighed 4 and 2 kg., respectively, and the one from the girl 800 Gm. Histological examination confirmed the diagnosis of embryonal carcinosarcoma. The first and third patients died a few hours after the operation. The second patient survived the operation and was given roentgen therapy, up to a total of 1,490 r. He was discharged as clinically cured 3 months later. Four months after the operation, however, he was blind from metastases in the chiasm. The fundi of the eyes were normal. The condition of the patient deteriorated rapidly, and he died 8 months after the operation.

The "Passing-Out" of Infants and Young Children: Cause and Treatment. P. Janson. München. med. Wchnschr. 99:779 (May 24) 1957 (In German) [Munich, Germany].

In infants and even more often in children between 1 and 6 years of age an emotional outburst accompanied by angry crying may result in arrest of breathing during the expiratory phase, followed by rolling of the eyes, thrashing about, cyanosis, and even loss of consciousness so that life seems threatened. The parents may become frightened and call the doctor, but after a few moments of "staying away" and after a deep inspiration the child regains consciousness. This "passing-out," "staying away," or rage fit is an emotional respiratory convulsion, usually in neuropathic children, and should not be overestimated. It should be controlled by pedagogic measures. It is a mistake to yield to the whims of these children for fear of eliciting a fit. When one develops, an energetic rather than a frightening attitude is necessary. A slap or a dash of cold water will not only abort an attack but will also reduce or prevent future ones. A change in environment or antineuropathic methods may be necessary if parents cannot apply such measures. Calcium and sedatives may prove effective, and in severe cases the author has obtained results with an injection of distilled water

OPHTHALMOLOGY

Retinopathy of Prematurity (Retrolental Fibroplasia) in Children in Whom the Disease has not Progressed to Complete Blindness, and the Subsequent Investigation of Cases of Myopia. I. D. R. Gregory. Brit. J. Ophth. 41:321-337 (June) 1957 [London].

A follow-up of 30 children with incomplete retrolental membranes was carried out. The children were known to have had retrolental fibroplasia in infancy, but some degree of vision could be expected. The clinical picture of these children was typical and included a myopic error of refraction in 26 children. The myopia varied from -2.5 to -18 D. Commonly the eyes were equally affected by retinopathy. Nystagmus was present in half of the patients, in 5 associated with eccentric fixation. Microphthalmic eyes were found in 14 children; these usually possessed little vision and frequently showed a convergent squint. Strabismus was present in 17 patients, secondary to the eye disease, which had led to gross visual impairment of the squinting eye. Opacities in the ocular media were frequently encountered. Three children with grossly damaged eyes showed corneal opacities, and one presented lenticular opacities; in two-thirds of the children vitreous opacities were evident. Malformations of the optic nerve-head were noted in 14 patients. Thinning, atrophy, and depigmentation of the retina were commonly encountered. Retinal detachment was evident in 14 patients and retinal folds were apparent in 6.

The noxious effect of the rubella virus on the developing eye occurs in the first 3 months of pregnancy, and the effect of prematurity on the eye takes place in the neonatal period. There appears to be a fundamental resemblance between the 2 in their effects on ocular development. The finding that retinopathy of prematurity is associated with myopia and that it has been possible to correlate myopia with prematurity suggests that prematurity is one of the factors which cause myopia. The new finding provokes further inquiry as to the nature

BOOK REVIEWS

Clinical Toxicology: The Clinical Diagnosis and Treatment of Poisoning. By S. Locket, M.B., B.S., M.R.C.P., Senior Physician, Oldchurch Hospital, Romford, Essex. With special sections on The Identification and Estimation of Some Common Toxic Substances, by W. S. M. Grieve, M.Sc., Ph.D., F.R.I.C., Biochemist, Oldchurch Hospital, and The Identification and Botanical Characteristics of Some of the More Frequently Encountered Poisonous Plants, by S. G. Harrison, B.Sc., Senior Scientific Officer, Royal Botanic Gardens, Kew, England. Cloth. $20. Pp. 772, with 27 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1957.

Although the hospital unit of which the author is in charge is primarily concerned with barbiturate poisoning, it has a growing reputation as a toxicologic center. For this reason, it draws cases of many types of poisoning from a wide area. Because the hospital is situated in a highly industrialized district, the physicians also see and treat many patients with industrial poisoning. This is one of the few books on clinical toxicology written by a physician in active clinical practice in the field of toxicology. The author emphasizes the fact that there is not a specific remedy or line of treatment for each type of poisoning, and only in a few cases does treatment involve intricate or unusual procedures not encountered in general practice. The basic treatment of poisoning is symptomatic and supportive. This book is designed to help the physician in the diagnosis and treatment of poisoning.

Part 1 relates treatment to the systems which may be involved, disorders that may occur, and the toxic agents responsible; part 2 describes the symptoms and treatment for individual toxic agents; and part 3 contains special sections on the identification and estimation of common toxic substances and the identification of poisonous plants contributed by experts in these fields. Parts 1 and 2 give the author's personal experience in the treatment of poisoning and the rationale of treatment. The material is illustrated with well-documented case histories, and an extensive bibliography is provided at the end of each chapter. Unfortunately, the classification of toxic agents is often confusing, as material concerning one agent or class of agents may be found in several sections of the book, thus entailing a great deal of cross reference. However, in cases of emergency, one can refer to the index of treatment. In addition there are three other indexes—author, plant names, and subject. This book is recommended as a basic reference in clinical toxicology.

International Congress of Gastroenterology. Fifth Meeting of l'Association des sociétés européennes et méditerranéennes de gastro-entérologie, London, July 18-21, 1956. Reprint from Gastroenterologia, vol. 86, nos. 3, 4 and 5 (1956). [In English and French.] Cloth. Pp. 766, with illustrations. S. Karger AG., Arnold Böcklinstrasse 25, Basel, Switzerland; (American agent—Mr. Albert J. Phiebig, P. O. B. 352, White Plains, N. Y.), 1957.

This book offers an unusual collection of papers on many important aspects of gastroenterology. The authors, in the main, are distinguished specialists from various countries. Part 1 is made up of contributions on nonmalignant conditions of the esophagus and deals with normal and abnormal motility of the esophagus, organic disorders, radiologic findings, clinical aspects of incompetence of the cardia, and premalignant conditions of the alimentary tract. Part 2 covers gastric physiology, hepatic coma, liver and biliary tract diseases, the cause and treatment of peptic ulcer, carcinoidosis, and celiac disease. There are papers dealing with precancerous conditions and their diagnosis, the relationship between peptic ulcer and hypoglycemia, and metabolic studies after extensive gastrointestinal resections. Part 3 is devoted entirely to ulcerative colitis.

While it can hardly be said that the essayists of the Congress presented any profound contributions to the subject of gastroenterology, the Congress served to bring together distinguished specialists from all over the world. The investigation and correlation of enviromental influences, which must be legion, in the study of diseases has barely begun. In gastroenterology, particularly, neglect in these areas has been responsible for a dearth of any substantial progress for some years in our knowledge of alimentary tract disease. This book provides an acceptable addition to the literature in this field. It is unfortunate, however, that the articles in the various foreign languages could not have been translated for the English-speaking members of the profession.

Gynecologic Surgery and Urology. By Thomas L. Ball, M.D., Assistant Professor of Clinical Obstetrics and Gynecology, Cornell University Medical College, New York. With foreword by R. Gordon Douglas, M.D., Professor of Obstetrics and Gynecology, Cornell University Medical College. Cloth. $20. Pp. 547, with 161 illustrations by Daisy Stilwell. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1957.

This volume embodies the essential teaching of the gynecologic staff of the New York Hospital–Cornell Medical Center. It is unique in its presentation of regional surgery as an advance from the

of the myopia and the mechanism of its production. More use of the term "retinopathy of prematurity" should be made, in view of the wide variety of clinical findings covered by this title.

THERAPEUTICS

Value of Troformone in Radiodermatitis. J. Lelièvre and A. Maschas. Presse méd. 65:1034-1035 (June 1) 1957 (In French) [Paris].

The authors have operated on 84 patients with radiodermatitis during the last 6 years, in all but 1 of whom the skin lesions followed x-ray treatment for corns, calluses, and plantar verrucae. Satisfactory information about the irradiation technique could not be obtained in many cases. Those in which it was available fell into 3 classes: (1) cases in which the x-ray dose was excessive or the filtration inadequate; (2) cases in which the technique was faultless but the patient, fearing operation, had falsely denied having previously had x-ray treatment; and (3) some 20 cases in which neither the technique nor the patient was at fault. Two more or less related causes may explain the occurrence of postradiation skin lesions in the third group: (1) the exceptional sensitivity to irradiation of the skin of the foot, which is poorly vascularized, and (2) the fact that the irradiated area is constantly subjected to irritation from the footwear and, when it is on the plantar surface, by the weight of the body. Corns, calluses, and plantar verrucae, in fact, usually appear at pressure points, and since, on the whole, x-ray treatment produces vascular sclerosis, it is easy to see that even a slight circulatory disturbance may precipitate the appearance of lesions. These same conditions of skin sensitivity and exposure to constant irritation also explain the difficulties encountered in treating radiodermatitis of the feet, especially when the lesions are extensive. The therapeutic dilemma lies in the fact that failure to excise all the injured tissue will be followed by recurrence, while wide excision will create difficult replacement problems. The skin is not elastic enough to permit approximation of the edges of the wound; a rotation flap may fail because of poor vascularization; and the cross leg flap procedure is open to objection, not only because it takes time and is painful but also because the skin used retains its original characteristics and never acquires the pressure-resistant capacity of genuine plantar skin.

The authors found that the problem presented in cases of this kind is greatly simplified by simple excision of the necrotic tissues followed by local applications of troformone (the trophic hormone of the pancreas). The effect of this treatment in 4 patients with extensive, exceptionally severe radiodermatitis was dramatic, amounting in each case to a restitutio ad integrum and enabling the patient to resume his normal activity within a short time. One of the patients, the only one who had been given radiotherapy for a condition other than corns, calluses, or plantar verrucae, had an area of fetid ulceration measuring 25 by 15 cm. at the site of an enormous fibrosarcoma on the right thigh. The tumor had been completely eradicated by large doses of x-rays, but some time after the treatment ulceration had begun in the irradiated area. The patient consulted several surgeons, but all of them believed that any attempt at operation would be certain to fail. He was then referred to the authors, and in May, 1954, they excised the necrotic tissue. Six weeks later, a clean surface was obtained by curettage and 10 days later treatment with troformone was started. A third and final operation was made necessary a week later because the necrosis had extended to an adjoining indurated area, but after this last operation recovery proceeded steadily, and by the end of September the defect was completely filled with sound tissue, pain had ceased, and the patient was leading a normal life.

Experience thus shows that when troformone therapy is associated with excision of sclerotic areas, which is essential to the success of the treatment, a complete cure can be expected in patients with radiodermatitis. The treatment is simple and painless; the reconstituted skin is practically normal and infinitely more resistant than a plantar graft; and, even if the reconstitution should prove inadequate in a given case, the restoration of the underlying tissues would make it easy to apply a free graft.

PATHOLOGY

Diffuse Scirrhous Carcinoma. E. Fischermann. Danish med. bull. 4:93-96 (May) 1957 (In English) [Copenhagen].

Diffuse scirrhous carcinoma is a form of cancer so far observed only in women. The term refers to its infiltrative growth. The primary tumor appears to originate in the breast, but the tumors have also been found in the bladder without a primary tumor in the breast. Although the tumor is small and progresses slowly, there may be extensive metastases in all smooth musculature. Two cases of diffuse scirrhous carcinoma in women aged 48 and 73, respectively, are reported. Medical aid was sought in each case for dyspeptic disorder, which was due to metastases in the smooth muscles of the gastrointestinal tract. The infiltration in the mammary tissue was limited, and a well-defined tumor was palpable. Diffuse scirrhous carcinoma is not a prestage of colloid cancer. In spite of its slow growth, the tumor is not only highly malignant but also insidious, as it does not give rise to symptoms until the metastases have become widespread.

BOOK REVIEWS

Clinical Toxicology: The Clinical Diagnosis and Treatment of Poisoning. By S. Locket, M.B., B.S., M.R.C.P., Senior Physician Oldchurch Hospital, Romford, Essex. Gynecologic Surgery and Urology. By Thomas L. Ball, M.D., Assistant Professor of Clinical Obstetrics and Gynecology, Cornell University Medical College, New York. With foreword by R. Gordon Douglas, M.D., Professor of Obstetrics and Gynecology, Cornell University Medical College. Cloth. $20. Pp. 547, with 161 illustrations by Daisy Stilwell. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1957.

This volume embodies the essential teaching
the gynecologic staff of the New Yor
Cornell Medical Center. It is unique
tation of regional surgery as an adv

These book reviews have been prepared by competent authorities and do not represent the opinions of any medical or other organization unless specifically so stated long-accepted organ specialty. That such does truly constitute an advance will be attested by all lighthearted gynecologists who have encountered unexpected and formidable complications in their work. The gynecologist of the future must be competent in the handling of urologic and intestinal complications and sequelae. His training must equip him accordingly, and such is the purpose of this book. It is unfortunate that so many gynecologists have had no training in urology, cannot use a cystoscope or urethroscope, have never inserted a ureteral catheter, and are equally incompetent in intestinal surgery. To many long in practice, this volume will come too late, but they can learn much from it and can institute among their trainees programs to insure future competence. Certainly, resident training should be extended to include this broader concept of gynecology.

Descriptions of operative procedures conform to the best standards and are preceded, step by step, with excellent reviews of the anatomy and physiology of the regions involved. The psychic and psychosomatic aspects of treating the female patient from early childhood to old age are well handled. Technically, there can be no criticism of the work. The large size pages with double columns add immeasurably to the readability of the book. The illustrations are well selected and arranged. The Author and his colleagues are to be congratulated in producing this excellent volume, one that should be available to all gynecologists and trainees in the specialty.

Ultramicro Methods for Clinical Laboratories. By Edwin M. Knights, Jr., M.D., Associate Pathologist, Director of Clinical Pathology and Blood Bank, Roderick P. MacDonald, Ph.D., Director of Clinical Chemistry and Research Advisor, and Jaan *Ploompuu, Chief, Division of Ultramicro Chemistry and Research Associate*, all of Harper Hospital, Detroit. Cloth. $4.75. Pp. 128, with 19 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1957.

The increase in the use of chemical tests for the diagnosis of disease has led to a number of problems. One important problem has been the difficulty in obtaining sufficient samples of blood or certain other body fluids for testing. This is especially true in the case of multiple testing in infants or children or in cases where venipuncture is impractical, such as in patients who are extremely obese or who are suffering from third-degree burns. The development of ultramicrotechniques for many blood tests has been a convenient method for surmounting this problem, since individual tests can be run on a few tenths of a milliliter of blood. These tests require special equipment, care, and techniques, and this book groups together the requirements for performing 18 or 20 clinical tests on an ultramicro scale. Discussions of the following determinations, tests, and procedures are included: potassium, sodium, calcium, chloride, inorganic phosphate, acid and alkaline phosphate. urea nitrogen, glucose, cholesterol, bilirubin, protein, and C-reactive levels; icterus index; carbon dioxide-combining power; thymol turbidity; cephalin flocculation; microflocculation tests for syphilis; microhematocrit readings; and electrochromatography. The chapters are organized to contain the principle of each test, a list of the apparatus and reagents needed, the procedure for performing the test, the normal values, and a short discussion of the meaning of each test. The first few chapters of the book are of a general nature, discussing such topics as the setting up of an ultramicrochemical laboratory, special equipment needed for performing the various tests, and the collecting and pipetting of blood. The volume contains a general index.

Outline of Fractures Including Joint Injuries. By John Crawford Adams, M.D., F.R.C.S., Consultant Orthopaedic Surgeon, St. Mary's Hospital, London. Cloth. $6.50. Pp. 248, with 218 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; E. & S. Livingstone, Ltd., 16 and 17 Teviot Place, Edinburgh 1, Scotland; 48 Bloomsbury St., London, W. C. 1, England, 1957.

This book presents a brief classification, the clinical features, and the treatment of the more common fractures. Discussion of fractures of the skull and facial bones is purposely omitted. The line drawings and x-ray illustrations are excellent. The discussion is necessarily limited. The recommended treatment is usually conservative. Certain recommended practices differ from the usual practice in orthopedic centers in the United States. On page 80, the excision of an avulsed fragment of a transverse vertebral process fracture is recommended. Such an operation, as primary treatment, is unusual and not often necessary. The discussion of fractures of the hip is excellent. With regard to fractures of the femoral shaft, traction and manipulation are recommended as routine procedures. The use of intramedullary nail fixation is mentioned for pathological fractures and for occasional use in cases of uncomplicated closed fractures. This is not in accordance with the present practice in the United States of using intramedullary nail fixation for practically all such fractures unless there is a contraindication to this method. There is an illustration of "gallows traction" for treatment of fractures of the femur in a young child; this method is similar to Bryant's traction used for this purpose in the United States. The illustration in the book does not show protection of the knees from hyperextension, and there is no discussion of the danger of vascular complications. The discussion of fractures of the metatarsals and phalanges is brief and probably oversimplified. Future editions should be slightly enlarged to include discussion of a wider range of fractures, including certain complicated common fractures. This book is primarily for students. It is of little value for the orthopedist, but it is an excellent quick reference book for a student or general practitioner.

QUERIES AND MINOR NOTES

PROCEDURES AFTER RADICAL MASTECTOMY

To the Editor:—*A 24-year-old woman, with two children, the last delivered in July, 1956, has had metastatic (axillary) adenocarcinoma of the left breast. The initial lesion was found in the upper outer quadrant. A radical mastectomy and axillary dissection were completed one week prior to the time of writing. If possible, adrenalectomy and hypophysectomy should be avoided. Chest x-ray and blood studies are normal. What is recommended for further management? Should x-ray sterilization or surgical removal of the gonads be done?*

M.D., Indiana.

Answer.—There is a marked difference of opinion in regard to the questions posed. This consultant feels that there is no adequate evidence that castration done as a complement to radical mastectomy is any better than castration done as a supplement when metastasis or recurrent disease becomes evident. Moreover, castration in a patient this age has the disadvantage of producing a severe menopause unnecessarily if the patient remains well. This patient should be irradiated over the internal mammary, supraclavicular, and axillary fields on the side which was operated on, and nothing further should be done now except for follow-up examinations.

STIMULATION OF INTESTINAL MOTILITY

To the Editor:—*Artificial stimulation of intestinal motility, as with neostigmine, has always been frowned upon by surgeons for postoperative use as being unphysiological. Recently a new product, pantothenyl alcohol, an alcohol of pantothenic acid, has been recommended for postoperative use to prevent distention after surgery. Would the use of this product be physiological in a case of gynecologic surgery where the intestine was only handled gently but not actually incised? Would its use be physiological in a case of intestinal surgery where the intestine was actually incised and sutured?*

James W. Davis, M.D., Leonard, Texas.

Answer.—The name pantothenic (acid) denotes the ubiquitous distribution of this material in foodstuffs. It is easily synthesized in significant quantities by bacteria found normally in the gastrointestinal tract, and it is a constituent of most cells in the body. Pharmacologically, pantothenic acid is involved in the coenzyme A system. A specific deficiency of pantothenic acid has been described in many laboratory animals; it has been produced in man by Bean and associates (*J. Clin. Invest.* 34:1085, 1955). Symptoms under these conditions varied but consisted chiefly of adrenal insufficiency; these occurred only after administration of a diet free of pantothenic acid and a potent antagonist to this vitamin. The gastrointestinal observations were confined to a depression of gastric secretion; there was no alteration in gastric motility. In studies by Gershberg and associates (*J. Nutrition* 39:107, 1949) on patients with a wide variety of deficiency and metabolic diseases, tolerance-excretion tests with pantothenic acid and alcohol of pantothenic acid administered intravenously failed to demonstrate a specific pantothenic acid deficiency, except in relation to pernicious anemia. Because of such observations and the wide distribution of pantothenic acid in the body and in food, the clinical existence of a deficiency of this substance would appear to be most unusual, even under preoperative and postoperative conditions. Thus, the rationale for the use of pantothenic acid would be determined more by its pharmacological action than by a presumed deficiency state.

Sclausero (*Gazz. med. ital.* 114:291, 1955; abstracted, *J. A. M. A.* 161:106 [May 5] 1956), Jacques (*Lancet* 2:861, 1951), and others have published favorable results concerning the use of pantothenic acid or pantothenol (alcohol of pantothenic acid) in the management of "intestinal paresis"; i. e., paralytic ileus in patients who had undergone abdominal or pelvic surgical procedures. Closer examination, however, suggests that time and coincidence, as well as the intravenously administered fluids, might have been equally important factors in the clinical response. Jacques's report, although based on only 16 patients with paralytic ileus, indicated that usually only one injection of pantothenic acid resulted in relief of the ileus. Other drugs, such as neostigmine and acetylcholine, previously had been ineffective, whereas pantothenic acid administered intravenously initiated prompt return of normal intestinal motility. Despite these reports the evidence is not yet entirely convincing. Further study of the usefulness of pantothenic acid in the management of postoperative distention seems desirable. Until favorable observations are reported by American s geons, the use of pantothenyl alcohol postoperati cannot be evaluated completely.

There would appear to be no physiological n pantothenic acid in "*a case of gynecologi* where the intestine was only handled gen actually incised." The early use of co

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

potential stimulating action upon the intestines after intestinal surgery would be regarded as unphysiological, since stimulation of the intestines at this stage is undesirable. The efficacy of drugs, such as neostigmine or acetylcholine, in postoperative paralytic ileus is highly questionable.

PREGNANCY AND HEREDITARY DISEASE

To the Editor:—*A 26-year-old woman, who has had three pregnancies in the past five years, had her first child succumb to lipid histiocytosis of phosphatide type (Niemann-Pick disease). Her second child was normal except for a minor congenital defect of the hand in the thumb. The third child, 8 months of age at time of writing, has stigmata consistent with Niemann-Pick disease, including an enlarged spleen and positive findings in the bone marrow. Is further pregnancy indicated?*

Robert E. Sandlin, M.D., Antioch, Calif.

Answer.—Niemann-Pick disease is a rare hereditary disease characterized by the accumulation of phosphatides in the reticuloendothelial system. Characteristic lipid-containing cells, known as Pick foam cells, may be found in all tissues. The condition is generally considered to be due to the action of a recessive gene.

If this is correct, both the father and the mother in question would be heterozygous or carriers of this gene. Each child that they have would have one chance in four of being affected and one chance in two of being heterozygous as its parents are. The fact that two affected children have already been produced would not lessen the chances of another child having the trait . Because the disease is fatal in affected children, the advisability of another pregnancy is very doubtful. The manner of preventing this, however, can best be determined by the parents in consultation with their physician. Irregular dominance has also been suggested as a mode of inheritance. If this is true in this instance, the chances of another affected child would not be lessened.

TEMPERATURE OF OPERATING ROOMS

To the Editor:—*What is the optimal temperature for an operating room? The particular operating room in question is located in the country and does not have air conditioning. Could not the windows to the outside air be opened during the summer months?*

M.D., New York.

Answer.—Common practice is to maintain operating rooms at a temperature of about 80 F (dry bulb). Humidity is important, and Clark, Orkin, and Rovenstine conclude that a better method is to use a wet-bulb thermometer and maintain the temperature at 75 F (wet bulb).

If an appropriate combination of temperature and humidity can be maintained, there is no objection to having the windows to the outside air open during the summer months, provided that two precautions are observed. First, the windows must be completely a effectively screened against all insects in the area. some areas it would be sufficient to screen agai flies and mosquitoes, but in other areas various small insects, such as midges, would have to be exclude requiring very fine mesh material. Second, the patie should be protected against drafts, which would ma it inadvisable to have the window open if there we enough wind to produce rapid air currents, ev though the outside temperature approximated tl ideal.

FAILURE OF EYELIDS TO CLOSE DURING SLEEP

To the Editor:—*The eyelids of a 4½-year-old boy not always close completely when he sleeps, leavi part of the eyeball exposed. Both eyes are usual involved. When the eyes are manually closed du ing sleep, the lids sometimes open again. In tl waking state there are no difficulties with volunta closure. The latter can be maintained against pre sure, and the tonus of the levators is good. Ther is no eye pathology and no exophthalmos, and th lids are well formed. Neurologically, the child entirely normal. His sleep is not interfered with b this defect, even when there is light. The mother i chiefly worried about possible trauma to the eye during sleep (from foreign bodies, insects, etc.). Ca the condition be disregarded?* M.D., New York.

Answer.—The failure of the eyelids to close durin sleep has been reported a number of times in th literature and is usually unassociated with pathology In the case cited, it would be interesting to not whether the eyes roll up sufficiently during sleep s that the corneas are completely covered by the partly closed lids. It would be the feeling of this consultant that, if the corneas are completely covered, no eventual trouble will arise from this situation. On the other hand, if the corneas are not covered, they may well dry out, erode, and ulcerate. In such a case, some bland ointment or artificial tears (methylcellulose) should be used each night on going to bed.

EXPOSURE OF EYES TO SOLDERING FUMES

To the Editor:—*A patient has been employed steadily for about 15 years as a tinsmith, and his job has been to solder and braze sheet metal and copper. Wh are the effects of muriatic acid and soldering fume on the cornea?*

M. L. Riccitelli, M.D., New Haven, Conn.

Answer.—The usual exposure of a tinsmith to soldering or brazing fumes should not involve any injury t the cornea. The fume composition would depend upo the flux used and the metal surface involved. When th soldering flux is muriatic acid or muriatic acid "cut" with zinc to form zinc chloride. the fume would contain, in addition to water vapor. a very small amount of hydrochloric acid and of zinc or copper, as the case may be, in the form of oxide. When as in brazing the flux is generally borax, this would be present in the fume. In neither instance would the concentration be such as to injure the cornea. Should the acid flux be spattered directly in the eye, an acid burn of the cornea would result, the severity depending upon the amount of acid involved and the duration of the contact. Years of observation of a large number of solderers have not disclosed any injuries to the cornea from fume exposure.

FIVE-YEAR MEDIAN

To the Editor:—*What is meant by the five-year median? Why is this statistic, which is used so much in comparing communicable disease reports, more advantageous than comparing reports year by year?*

M.D., Illinois.

Answer.—A five-year median is another expression of an average. It is the middle one of an array of five figures, usually those for five consecutive years. When a five-year median is used, there are always two figures less and two greater than the middle or median figure. Because many infectious diseases fluctuate widely in incidence from one year to another, it is considered desirable to compare a current figure with one that is less influenced by fluctuations. For this reason, median averages are preferred to the common or mean averages, the latter being subject to the influence of extreme variations which would result if just one year, of the five being reported, had an unusually high or low incidence. While it would not be misleading to compare a current figure with each of the previous five years, it usually is not done in current publications because of limitations of space. Furthermore, by using a median more valid comparison can usually be made.

CATARACT SURGERY IN A DIABETIC

To the Editor:—*Inasmuch as postoperative intraocular bleeding is commoner in recently controlled diabetics, when cataract surgery is required upon an uncontrolled diabetic, is it preferable to go directly ahead with the surgery and disregard the diabetic status until the postsurgical period?*

Herbert J. Rosen, M.D., Dover, N. J.

Answer.—It is good practice to stabilize the blood glucose in a diabetic who is to undergo cataract surgery. Since this operation is nearly always elective, sufficient time for this purpose is usually available. A sense of well-being in the patient is a valuable adjunct in ocular surgery. If circumstances are such that previous regulation is impossible and cataract extraction is necessary, it is better to operate with the blood glucose level a little elevated than to attempt to lower it suddenly. The latter procedure, especially if it produces a mild insulin shock, is likely to make an elderly patient restless, uncomfortable, and perhaps uncooperative. This, of course, increases the likelihood of hemorrhage or other surgical complication.

ETHER AND ALOPECIA

To the Editor:—*In the practice of anesthesiology one is frequently confronted with the statement that "ether makes the hair fall out." Is there any literature giving a scientific opinion on the subject?*

George T. Henderson, M.D., Bound Brook, N.J.

Answer.—None of the reference books on toxicology to which this consultant has access give ethyl ether as a cause of alopecia. Ether is said to be inert to metabolic processes and is largely eliminated in the expired air. In industry, 500 ppm of ethyl ether is the allowable maximum concentration which is said not to cause dizziness or injurious effects. Von Oettingen in his book "Poisoning" (New York, Harper & Brothers, 1952) gives a long list of symptoms from which workers industrially exposed to ether may suffer, but loss of hair is not among them. Patients undergoing surgical procedures that require ether anesthesia may be in poor health and debilitated, and this may cause "the hair to fall out." The patient or the relatives may attribute to the ether the loss of hair which is actually due to poor health.

EFFECT OF CITRATE AND POTASSIUM ON BLOOD

To the Editor:—*A patient is to receive an intravenously administered injection of 40,000,000 units of potassium penicillin G daily for three to six weeks. If the penicillin is buffered with sodium citrate, would there be enough citrate to affect blood coagulation? Would there be enough potassium in potassium penicillin G to affect the blood potassium?*

M.D., West Virginia.

Answer.—Assuming that the penicillin is administered by slow intravenous drip and that renal function is adequate, the blood potassium should not be raised to dangerously high levels by the administration of 40,000,000 units of potassium penicillin G daily. Further, since citrate is metabolized very rapidly by the liver, citrate intoxication does not occur unless the hepatic function is seriously impaired. In such an event the toxic effects are those of hypocalcemia. Prolonged blood coagulation does not occur *in vivo*, since it develops only when the blood calcium is reduced to 2.5 mg. per 100 cc. or less, a level incompatible with life.

AMYOTROPHIC LATERAL SCLEROSIS

To the Editor:—*Please supply information regarding a toxoid treatment for amyotrophic lateral sclerosis.*

Joseph M. Silver, M.D., Fitchburg, Mass.

Answer.—This consultant has no information regarding a toxoid treatment for amyotrophic lateral sclerosis. At the present time, the etiology of this disease has not been ascertained, and there is no known specific treatment for it.

SEVERED RECURRENT LARYNGEAL NERVE

To the Editor:—*What is the best surgical technique of uniting the cut ends of a severed recurrent laryngeal nerve?*

M.D., New York.

Answer.—A severed recurrent laryngeal nerve can be united, as any other small nerve, by meticulous approximation of its ends with extremely fine silk sutures, such as are used in eye surgery. Unfortunately, however, this consultant knows of no report of a severed nerve which has recovered its function after anastomosis. Anastomosis of the nerves was once advocated by Dr. Lahey, but no reports of successful return of function were made in the case of patients who had had the nerve actually severed. The chief advantage of exploration of the recurrent nerve after its paralysis has been observed is to remove any ligatures which might have inadvertently been placed on the nerve. If such a ligature is removed promptly, the nerve will recover its function.

VAGINAL CHILDBIRTH AFTER CESAREAN SECTION

To the Editor:—*A 30-year-old woman has presented herself for prenatal care. She has had four pregnancies, three with delivery by the vaginal route, but the second pregnancy was complicated by third trimester bleeding, and a cesarean section was done, with delivery of a living 4-lb. baby. Can it be assumed that the cesarean scar has healed so well as to be no factor in the approaching delivery, or have the last two deliveries through the birth canal tested the scar to the limit? Are there any statistics on uterine-scar ruptures after several uneventful deliveries from below?*

Lester Lando, M.D., Monsey, N. Y.

Answer.—The delivery of babies through the birth canal after previous cesarean section is no valid test of a uterine scar. Serious and fatal uterine ruptures have occurred after such deliveries in women who had been subjected to previous cesarean sections. If it is decided that this patient is to be delivered from below, she should be cautioned to come into the hospital at the first sign of impending labor. The labor should be carefully supervised, so that any unusual tenderness of the uterus can be ascertained early and properly evaluated. The child should be delivered by outlet forceps when dilatation is complete and the head has reached the pelvic floor.

Eastman reports that on his service the incidence of uterine rupture after previous cesarean section is 2.1% —1% in pregnancy and 1.1% in labor. The maternal mortality after uterine rupture is at least 10%. Thus, the mortality from uterine rupture in women who have had previous abdominal deliveries is about 0.2%, about twice the average risk of cesarean section today. Although this increased hazard is not great, uterine rupture entails an inordinately high infant loss and the probable termination of future childbearing. Thus, t indication for the initial abdominal delivery must given the greatest consideration, for the uterine sc may well make future childbearing an abnormal fu tion.

RECTAL INCONTINENCE

To the Editor:—*Is any kind of pouch or bag mac which would be helpful when there is complete lo of sphincter control in the rectum?*

George B. Lawson, M.D., Roanoke, Va.

Answer.—There is no effective bag or appliance fo the control of fecal material in rectal incontinence. Tl only effective solution is a successful repair of tl defect.

INGESTION OF FOREIGN BODIES

To the Editor:—*In answer to a query about the i gestion of foreign bodies (*The Journal*, July 2 1957, page 1422), the consultant says: "Sharpl pointed radiopaque foreign bodies that do not leav the stomach or pass through the duodenum occasionally require removal by transgastric means."*

What of the magnetic removal of such objec (Equen and others: Nail in Duodenum Removed by Magnet, J. A. M. A. 135:432 [Oct. 18] 1947; Equen: *Magnetic Removal of Foreign Bodies, Springfield Ill., Charles C Thomas, Publisher, 1957)? In the latter publication the author summarized more thar 200 cases of removal of ferrous bodies from the upper gastrointestinal tract with the magnet withou a single fatality. When the patient is an infant oi small child, removal of such bodies by transgastric or transduodenal means is both difficult and dangerous, involving perhaps a week of hospitalization and intravenously given fluids. Just giving fluids into the small veins of such a patient is no light undertaking.*

L. Minor Blackford, M.D.
104 Ponce De Leon Ave. N. E.
Atlanta 8, Ga.

The above comment was referred to the consultant who answered the original query, and his reply follows.—Ed.

To the Editor:—*The removal of ferrous foreign bodies from the upper part of the gastrointestinal tract by magnet has been proved feasible and satisfactory by Dr. Equen, who probably has had the largest experience of anyone with this method. It is difficult to assess the relative hazards of the use of the magnet and of surgical procedures. However, little additional hazard or difficulty should be encountered in the few instances in which intravenous administration of fluids is indicated (Miles and Harris: Venostomy, an Improved "Cut-Down" Procedure in Infants and Children, J. A. M. A. 161:619-621 [June 16] 1956).*

A. M. A. ENDORSES SPECIAL BROADCAST BAND FOR PHYSICIANS

The American Medical Association believes that the future of medical practice calls for the setting aside of special radio bands for emergency use by doctors and of noncommercial FM channels for educational purposes.

The Association has filed a brief with the Federal Communications Commission on endorsing the allocation nationwide of six 30-kilocycle channels around the 161 megacycle area in the radio spectrum for remote pickup broadcast stations on an exclusive basis. Similarly, it urged use of several channels in the same area for educational broadcasts.

"The Association believes that the use of numerous remote pickup broadcast stations in conjunction with noncommercial FM broadcast stations represents an effective method of developing the potential of educational programs," the A. M. A. informed the FCC. "To make full utilization of remote pickup broadcast stations as an integral part of broadcast programs, it is essential that adequate clear channels be reserved for these remote pickup broadcast stations."

The brief also notes that the present availability of radio communication channels for the medical profession is very limited and that the "value of this medium in the practice of medicine has not been fully realized."

In a separate brief, the American Hospital Association asked the FCC to set aside additional channels for hospitals and hospital associations for similar purposes. The AHA cited an urgent need for special communications for day-to-day operations as well as disaster conditions.

AHA also pointed out the need for effective communications with ambulances and automobiles of staff physicians and surgeons.

SECRETARY FOLSOM URGES PUBLIC SUPPORT FOR SALK VACCINE CAMPAIGN

Urging public support for the Salk poliomyelitis vaccine campaign, Secretary Folsom points out that "the means to avert the suffering and anguish caused by polio are at hand," and "it is possible to give paralytic polio a knockout blow within the next year."

Cooperating in the drive to induce the public to protect itself are the American Medical Association, State and Territorial Health Officers, the Advertising Council, and the National Foundation for Infantile Paralysis, as well as the U. S. Public Health Service.

The Secretary of the Department of Health, Education, and Welfare reported that paralytic poliomyelitis had decreased a spectacular 80% during the last two years but that "millions of Americans under 40 still have not received full vaccine protection and thus are needlessly risking disability or even death."

Paralytic cases so far this year have totaled 1,576, in contrast to 7,886 cases for the comparable period two years ago, before widespread use of Salk vaccine, and 5,241 cases last year. Although the vaccine is designed to prevent paralytic poliomyelitis, the total number of cases this year also has decreased to 4,851 in contrast to 21,667 two years ago, 12,156 a year ago, and an average of 24,928 over the past five years.

Mr. Folsom reviewed the ups and downs of the Salk vaccination campaign and the reasons behind the nationwide drive, started early this year, to protect the American public.

He pointed out that a year ago production was cut back because use of the vaccine had dropped sharply and supplies piled up in warehouses. Subsequently the A. M. A. initiated its campaign, and by last spring demand had risen and again the vaccine was in short supply and many community and industry vaccination campaigns were postponed.

Now, the Secretary said, supplies are beginning to pile up again, "and this is the best time for medical societies, local health departments, schools, industries and individual citizens and physicians to make sure that everyone who needs protection gets it. If unvaccinated persons will start now, they can get the full schedule of three doses before the next polio season begins."

Mr. Folsom, noting that more than 37 million Americans under 40 have received no vaccine, and 44 million have had only one or two doses, said:

(Continued on next page)

'LANOXIN'®
brand
DIGOXIN

formerly known as Digoxin 'B.W. & Co.'®

"If one digitalis agent were to be recommended for its adaptability to the many and varied clinical contingencies, we believe Digoxin would be [a] drug of choice."

Lown, B., and Levine, S. A.:
Current Concepts in Digitalis Therapy, Boston,
Little, Brown & Company, 1954, p. 23, par. 2.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

"It will be a tragedy if, simply because of public apathy, vaccine which might prevent paralysis or even death lies on the shelf unused."

In connection with the Secretary's appeal, Surgeon General Burney gave this summary of the situation:

Incidence.—Only 63 cases of paralytic poliomyelitis among the 28 million persons who have received three shots of vaccine, and not all of these confirmed. Three doses are estimated to reduce paralytic poliomyelitis incidence by up to 90%.

Vaccine Use.—More than 72 million Americans already have received one or more doses—out of a total population of 109 millions persons under 40. Estimates indicate: Of the 67 million persons in the priority group, under 20 years of age and expectant mothers, 25 million have received all three injections, 22 million 2 injections, 11 million 1 injection, and 9 million no vaccine. Attention should be given particularly to vaccinating teenagers. Of the 42 million persons 20 through 39 years old, 14 million have been vaccinated—3 million with 3 doses, 5 million with 2 doses, and 6 million with 1 dose. But 28 million adults have had no vaccine.

FOOD AND DRUG ADMINISTRATION REPORTS RISE IN PENICILLIN REACTIONS

The fifth annual Symposium on Antibiotics heard a report from Dr. Henry Welch, chief of the Food and Drug Administration division of antibiotics, that serious reactions to penicillin are on the increase. Since 1945, Dr. Welch told the meeting, isolated reports of reactions with a relatively high percentage of fatalities have been appearing in medical literature.

The FDA survey, covering the principal antibiotics, showed a substantially higher number of reactions to penicillin than to other antibiotics. A third of the reported reactions to all antibiotics were classified as life-threatening and about nine-tenths of these were attributed to penicillin.

His report has this comment: "The trend of increase in serious reactions, especially from penicillin given by intramuscular injection, shows there should be a clear-cut indication of need before the drug is administered. The study of case histories indicates that there has not been indiscriminate use of penicillin by physicians."

Dr Welch said the number of reactions to penicillin is still small when considering that millions of persons receive it each year and that it has saved many lives. An increase is to be expected, he added, in the wise use of a highly antigenic substance.

HEALTH COUNCIL LOOKING INTO CAREERS IN HEALTH

A new commission, this one sponsored by the National Health Council, is looking into ways "to meet the acute need for qualified health personnel in the United States." It is called the Commission on Health Careers with Dr. Leonard A. Scheele, former surgeon general of the Public Health Service, as chairman. Since leaving the government, Dr. Scheele has been president of Warner-Chilcott Laboratories.

The commission is made up of persons in industry and other fields. It has one other physician member, Dr. Herman Hilleboe, health commissioner for New York State. Another member is former Sen. Herbert Lehman (D., N. Y.), who was prominent in health and welfare legislation while in the Senate.

Basil O'Connor, president of the National Health Council, believes that lack of manpower "poses the biggest threat not only to our present health services but to the future progress of medical science." He said workers in more than 150 health occupations also guard the well-being of the public and the great majority of these posts are "dangerously understaffed."

ASIAN INFLUENZA ADVISORY GROUP REPORTS ON VACCINATIONS

Adults should be given a full cubic centimeter of the Asian influenza vaccine for best results, while children under 5 may have two inoculations of 0.1 cc. This is the latest recommendation of a Public Health Service advisory committee on influenza vaccine which reported to Surgeon General Burney. The committee said the children's doses should be given a week apart, injected intracutaneously.

The PHS announcement declared in part: "The committee recommended that only the subcutaneous inoculation of 1.0 cc. be endorsed for general use in adults. It noted that in certain special instances 0.1 cc. given intracutaneously might be used advantageously but physicians using this method must rely on their own judgment regarding its usefulness in each instance. The use of two 0.1 cc. intracutaneous doses, separated by at least one week in children under the age of five, as has been recommended by the American Academy of Pediatrics, was recognized as an acceptable procedure."

71,570 REHABILITATED PLACED ON JOBS

According to the Office of Vocational Rehabilitation, 71,570 disabled, a record number, were restored to useful work in the last fiscal year through public training-treatment programs. The last fiscal year's total was 66,296.

OVR Director Mary E. Switzer said the increase "was not as great as had been expected, but was encouraging since 41 of the 52 states and territories showed increases."

Information comes from state rehabilitation agencies, which work in cooperation with OVR, and private agencies, which receive some OVR support. Public agencies are credited with placing 70,939 in jobs after helping them to overcome difficulties, and 631 were placed through the efforts of voluntary, nongovernment organizations.

An additional 145,000 disabled were receiving rehabilitation services from public agencies as the year ended, most of whom are expected eventually to be restored to productive work. Pennsylvania's total of 6,024 restored to jobs led the nation.

OVR estimates that those rehabilitated by public agencies (70,939) in the 12 months preceding last July 1 will increase their annual earnings from $18,900,000 to about $127,600,000 their first ye the job, and will add 109 million man-hours t nation's production potential.

two reasons for the growing use of Serpasil in everyday practice

Serpasil can always be considered
***first** in hypertension*

Alone, reduces blood pressure, slowly and safely, in about 70 per cent of mild to moderate cases.[1] *As a "primer,"* Serpasil can advantageously be used to begin therapy, however severe the case, to adjust the patient to the physiologic setting of lower pressure. *As a "background" agent throughout other therapy,* Serpasil permits lower dosage of more potent agents, thus minimizing side effects. *Average Dose:* two 0.25-mg. tablets daily for one week, then maintenance on 0.25 mg. or less daily.

[1] Coan, J. P., McAlpine, J. C., and Boone, J. A.: J. South Carolina M. A. 51:417 (Dec.) 1955.

One of the safest, least toxic and most effective agents for
